requirements for the degree of Doctor of Philosophy.

ABSTRACT

Let $\text{MC}(F_g)$ denote the group of homeomorphisms modulo isotopy of
the $g$-holed torus $F_g$; let $\mathcal{P}'(F_g)$ denote the collection of isotopy
classes of closed one-submanifolds of $F_g$, no component of which bounds
a disc in $F_g$. Max Dehn gave a finite collection of generators for $\text{MC}(F_g)$; he also described a one-to-one correspondence between $\mathcal{P}'(F_g)$ and a
certain subset of $\mathbb{Z}^{6g-6}$, denoted $\Sigma_g$. We describe the natural action of
$\text{MC}(F_g)$ on $\mathcal{P}'(F_g)$ by computing the corresponding action of a collection
of generators for $\text{MC}(F_g)$ on $\Sigma_g$. This action has an intricate but
tractable description as a map from $\Sigma_g$ to itself. We use this description
to give an algorithm for solving the word problem for $\text{MC}(F_g)$. This
computation has applications to several problems in low-dimensional
topology and dynamics of surface automorphisms.

Let $F_g$ denote the $g$-holed torus. We define a **multiple curve** in $F_g$ to be an isotopy class of (unoriented) one-submanifolds embedded in $F_g$, no component of which bounds a disc in $F_g$. In 1922, M. Dehn [5] described a one-to-one correspondence between the collection of multiple curves in $F_g$ and a subset of $2^{6g-6}$. Such a correspondence will be called a **parametrization** of multiple curves, and the corresponding subset of $2^{6g-6}$ will be called the collection of parameter values.

The **mapping class group** of $F_g$, denoted $MC(F_g)$, is the group of orientation-preserving homeomorphisms of $F_g$ modulo isotopy. An element of $MC(F_g)$ is called a **mapping class** on $F_g$. In 1938, Dehn [6] exhibited a finite set of generators for $MC(F_g)$ of a certain geometrical type, which are now called Dehn twists. Thus, a mapping class may be described by a word whose letters are Dehn twists. This word is not uniquely determined as there are relations in $MC(F_g)$ amongst such words.

An orientation-preserving homeomorphism $\tau$ of $F_g$ acts on an (unoriented) one-submanifold $c$ embedded in $F_g$ by taking the image of $c$ under $\tau$, and this gives a well-defined action of $MC(F_g)$ on the collection of multiple curves in $F_g$. A natural problem arises - to compute the action of Dehn twist generators for $MC(F_g)$ on parameter values of multiple curves, thus describing the action of $MC(F_g)$ on multiple curves in $F_g$.

In this thesis, we will explicitly compute this action for a fixed choice of parametrization. We will obtain a faithful representation of $MC(F_g)$ as a group of transformations on the collection of parameter values, and we will describe an efficient algorithm for solving the word problem for a certain collection of Dehn twist generators for
MC(F_g). This computation also has direct applications to several problems in low-dimensional topology and dynamics of surface automorphisms, as we shall see. In this section, we will briefly describe how this computation is performed for the surface F_2 and indicate some of the techniques employed. We also give a brief account of some of the history.

If c is a simple closed curve in F_g, then the right and left Dehn twists, denoted $\tau_c^{\pm 1}$, are defined by cutting F_g along c, twisting by $\pm 2\pi$ and regluing. The definition of the direction of the twist depends only on the orientation of the surface F_g. (We will give a more detailed definition in Section 3.) Thus, if c and d are the simple closed curves in the surface F_1 indicated in Figure 1.1a, then $\tau_c^{+1}d$ and $\tau_c^{-1}d$ are the curves pictured in Figures 1.1b and 1.1c, respectively. In fact, MC(F_1) is easily shown to be generated by $\tau_c$ and $\tau_d$. For surfaces of higher genera, R. Lickorish [11] has independently refined Dehn's original set of generators of MC(F_g) to a more useful set of 3g-1 curves along which to perform Dehn twists. These curves are pictured on the surface F_2 in Figure 1.2. (The extensions to higher genera will be discussed in Section 3.)

Figure 1.1
$\text{MC}(F_1)$ can be shown to be isomorphic to the group of two-by-two integral matrices of determinant one, and one has a complete set of relations between $\tau_c$ and $\tau_d$. For a closed surface of genus two, J. Birman and M. Hilden [3] have given a complete set of relations amongst the Lickorish generators. For closed surfaces of arbitrary genus, W. Thurston and A. Hatcher [19] have given an algorithm for constructing a complete set of relations for $\text{MC}(F_g)$, but their results are quite complicated.

Just as Lickorish independently refined Dehn's original set of generators, Thurston [17] rediscovered Dehn's parametrization for multiple curves. Dehn's parametrization apparently was not published, but appears in some lecture notes in the Archives of the University of Texas at Austin [5]. (I am grateful to J. Stillwell for supplying me a translation of these notes from the original German.) We will refer to this parametrization as the Dehn-Thurston parametrization.

The Dehn-Thurston parametrization depends on several choices of convention, one of which is a certain decomposition of the surface $F_g$. We define a pants decomposition of $F_g$ to be a collection $\{K_i\}$ of disjoint simple closed curves in $F_g$ so that each component $C$ of $F_g \setminus \bigcup{\{K_i\}}$ is topologically a sphere with three disjoint closed discs deleted. Every
surface $F_g$ has a pants decomposition consisting of $3g-3$ curves. (In fact, every pants decomposition of $F_g$ has exactly this many curves.) Some examples of pants decompositions of the surface $F_2$ are indicated in Figure 1.3. A pair of pants is a sphere minus the interiors of three disjoint closed discs; it is a planar surface with boundary having three boundary components. Note that we do not require the closure of the set $C$ to be, topologically, a closed pair of pants; see Figures 1.3b and 1.3c. We only require that $C$ itself be the interior of a pair of pants.

![Figure 1.3](image)

Very roughly speaking, the Dehn-Thurston parametrization for multiple curves counts how many times the curve crosses each of the "pants curves" $K_i$, and how many times it twists around while going from one component of $F_g \setminus \bigcup \{K_i\}$ to another.

Corresponding to the pants decomposition in Figure 1.3a (plus some other choices of convention), the Dehn-Thurston theorem gives a
parametrization of the collection of multiple curves in $F_2$. Comparing Figures 1.2 and 1.3a, we note that three of the Lickorish generating curves are curves in the pants decomposition. It turns out that the actions on the Dehn-Thurston parameter values of Dehn twists along these curves are simple linear maps and thus trivial to compute. This fact was noted by Dehn.

However, the action of Dehn twists along the other two curves in the Lickorish generating set are not nearly so simple. To tackle the problem of computing them, we note that these curves are curves in the pants decomposition indicated in Figure 1.3c. If we had a way of computing the Dehn-Thurston parameter values relative to the pants decompositions in Figure 1.3c from the parameter values relative to the pants decomposition in Figure 1.3a and vice-versa, then we would be able to compute the action of each of the Lickorish generators relative to the original pants decomposition in Figure 1.3a. This is in fact what we do. The philosophy comes from linear algebra: if a transformation (a Dehn twist) is hard to compute, change basis (pants decomposition).

We pass from Figure 1.3a to Figure 1.3c by means of two elementary transformations, which we now describe. The first one takes us from the pants decomposition in Figure 1.3a to the one in Figure 1.3b. It may also be described as the transformation pictured in Figure 1.4b; cutting along the right-most and left-most curves in Figures 1.2a and 1.3b gives us the surface pictured in Figure 1.4b. The second transformation takes us from the pants decomposition in Figure 1.3b to the one in Figure 1.3c. It may also be described by two applications of the transformation pictured in Figure 1.4a; cutting along the nullhomologous curves in Figures 1.3b and 1.3c gives us two copies of the surface pictured in Figure 1.4a.
We will call the transformation pictured in Figure 1.4a and 1.4b the first and second elementary transformations, respectively. Thus, the computation of the action of $\text{MC}(F_2)$ on the collection of multiple curves in $F_2$ is reduced to the computation of the two elementary transformations. In fact the same procedure works for surfaces of arbitrary genus; there exists a collection of pants decompositions of $F_g$, all related by sequences of elementary transformations, so that each of the Lickorish generating curves is a pants curve in at least one of the pants decompositions.

Our problem reduces in general to the computation of the two elementary transformations. I am grateful to D. Gabai [9] for showing this reduction, which he discovered.

This thesis is concerned with computing the two elementary
transformations. The first elementary transformation is relatively easy and can be done by actually isotoping curves and arcs about on the torus-minus-a-disc. This has been done successfully by Gabai. The second elementary transformation requires much more work, yet the techniques we develop to handle the second elementary transformation also apply to the first elementary transformation.

At this juncture of the exposition, it would be pointless to give the formulas describing the two elementary transformations. The reader wishing to see what the formulas involve is encouraged to read Sections 2 and 3 and then skip to Section 8 where these formulas are presented and some applications discussed. We describe briefly here the nature of the results we obtain.

The subset of $\mathbb{Z}^{6g-6}$ that parametrizes the collection of multiple curves in $F$ naturally embeds as a subset of $\mathbb{Z}^n$ in some high-dimensional Euclidean ball $B^n$. To each element $\psi$ of $MC(F)$ corresponds a finite simplicial decomposition $K_\psi$ of $B^n$. $\psi$ acts simplicially as a map of $K_\psi$ to itself, and, what is more, it acts like an integral matrix on each top-dimensional simplex of $K_\psi$. We call such a transformation a piecewise-integral transformation. Our main theorem may be stated as follows.

**Theorem 1.1:** The action of $MC(F)$ on the collection of multiple curves in $F$ admits a faithful representation as a group of piecewise-integral transformations.

We prove the theorem by actually computing the action of $MC(F)$ on the parameter values corresponding to multiple curves relative to a fixed parametrization. We then note that the action is piecewise-integral and check faithfulness.

We remarked previously that our explicit computations in fact
describe the action of words in Lickorish's generators on the collection of multiple curves in $F_g$, rather than the action of $\text{MC}(F_g)$ itself. We use this fact to our advantage by applying our theorem to give a practical algorithm for solving the word problem in Lickorish's generators. Using the Alexander Lemma, one can easily show (see Proposition 8.1) that a mapping class on $F_g$ contains the identity if and only if it fixes the isotopy classes of a certain collection of $2g+1$ simple closed curves. This result proves the faithfulness of our representation. Moreover, one can check if a word in Lickorish's generators is the identity in $\text{MC}(F_g)$ simply by computing whether the word fixes $2g+1$ particular multiple curves. This fact immediately gives the following Corollary.

**Corollary 1.1:** There is a practical algorithm for solving the word problem in Lickorish's generators for $\text{MC}(F_g)$.

An outline of this thesis is as follows: In Section 2, we present the Dehn-Thurston parametrization of multiple curves and derive a new parametrization of such curves that is more useful for our purposes, and we give some basic definitions. In Section 3, we give some additional basic definitions, and we reduce our main computation to the computation of the two elementary transformations. These are in turn performed in Sections 6 and 7. Section 5 develops the main technical tools used in Sections 6 and 7. Section 4 contains results about one-submanifolds immersed in surfaces which are used in Section 5; these results have an independent interest as well. In Section 8, we discuss the formulas derived and mention several applications.

I should remark that though we have restricted attention to the action of $\text{MC}(F_g)$ on multiple curves in $F_g$, the computations in this thesis in fact apply more generally to any surface of negative Euler characteristic.
I should also remark that there is a natural generalization of multiple curves called measured train tracks. Furthermore, the (discrete) set of multiple curves sits inside the (connected) space of measured train tracks in a natural way. In fact, our computations can be made to describe the action of $MC(F_g)$ on the space of measured train tracks. Thus, though we restrict our attention in this thesis to the essentially combinatorial setting of multiple curves, our results apply more generally to the analytical setting of measured train tracks. This point of view will be discussed in Section 8.
Let $F$ be a compact oriented surface. If $i$ is an embedding of some one-manifold $O$ into $F$, then we refer to the subset $i(O) \subset F$ as a one-submanifold embedded in $F$. Thus, a one-submanifold embedded in $F$ is regarded as an unoriented point set. Recall that an embedding $i(O)$ of a one-manifold $O$ in $F$ is proper if $i(O) \cap F = \partial F$. Though we are primarily interested in embeddings of closed one-submanifolds in $g$-holed tori, the considerations of this section lead to the more general setting of one-submanifolds properly embedded in a compact oriented surface of negative Euler characteristic $\chi(F)$. We thus consider this more general setting from the outset. Note that the requirement of a negative Euler characteristic excludes precisely four surfaces: the torus, sphere, disc and cylinder.

Let $c$ be a one-submanifold properly embedded in $F$. Note that components of $c$ are either simple closed curves in $F$, called "closed components", or arcs properly embedded in $F$, called "arc components". We will say $c$ is essential if no arc component of $c$ can be homotoped (through proper embeddings) into $\partial F$; furthermore, no closed component of $c$ can bound a disc in $F$. If a component of $c$ can be homotoped into $\partial F$, we say that it is boundary-parallel. We will require a notion of isotopy that is slightly stronger than proper isotopy and weaker than isotopy rel $\partial F$.

Choose, once and for all, a point $x_i$ in each boundary component $C_i$ of $F$. We allow a proper isotopy to move points about in $C_i \setminus x_i$, but it must keep the point $x_i$ fixed. A multiple arc in $F$ is such a proper isotopy class of essential one-submanifolds of $F$. We define a multiple curve in $F$ to be an isotopy class of essential closed one-submanifolds in $F$. (Note that boundary-parallel closed components of multiple arcs and curves are allowed.) We denote the collection of multiple arcs in $F$ by $\mathcal{G}^p(F)$ and describe an explicit parametrization for multiple arcs in this section. A parametrization for multiple arcs is a one-to-one correspondence between
\( \mathcal{P} (F) \) and some subset of \( \mathbb{Z}^n \), for some \( n \). We will refer to any subset of \( \mathbb{Z}^n \) as an integral lattice.

In order to parametrize multiple arcs in \( F \), we must choose a certain decomposition of the surface \( F \). A pair of pants is a closed disc \( D \) minus the interiors of two disjoint closed discs contained in the interior of \( D \). A pants decomposition \( \{ K_i \} \) of \( F \) is an embedded closed one-submanifold in \( F \) so that each component \( C \) of \( F \setminus \cup \{ K_i \} \) is the interior of a pair of pants. We do not require the closure of the set \( C \) in \( F \) to be an embedded pair of pants. Some examples of pants decompositions are given in Figure 2.1. Note that the boundary components of \( F \) are necessarily curves in a pants decomposition. One constructs such a pants decomposition \( \{ K_i \} \) by taking a maximal family of disjointly embedded simple closed curves in \( F \), no two of which are freely homotopic. Two unoriented simple closed curves in \( F \) are said to be parallel if they are freely homotopic. One can check that there are \( M = |\chi(F)| \) pairs of pants in a pants decomposition and that the number of components of \( \{ K_i \} \) is given by

\[
N = \frac{1}{2} (3|\chi(F)| + \text{(number of boundary components of } F)).
\]
We begin with a discussion of the standard pair of pants $P$, which is regarded as oriented, with the boundary components $\partial_k$ numbered as in Figure 2.2 and with the arcs $w_k \subset \partial_k$ as pictured, $k=1,2,3$. We refer to these arcs as windows. Two arcs $c$ and $d$ in $P$ with $\partial c$ and $\partial d$ contained in windows are said to be parallel if there is a disc $D$ embedded in $P$ with $\partial D$ contained in $c \cup d \cup \text{Interior}(w_1 \cup w_2 \cup w_3)$.

It is shown in [8, Expose 2] that two essential one-submanifolds in $P$ with no boundary-parallel components, say $c$ and $d$, satisfy
\[ \text{card}(c \cap \partial_k) = \text{card}(d \cap \partial_k), \quad k=1,2,3, \]
if and only if there is a homeomorphism fixing $\partial P$ component-wise and carrying $c$ to $d$. Moreover, any such homeomorphism is isotopic rel $\partial P$ to a map that is the identity off an annular neighborhood of $\partial P$. In general, if $\gamma$ and $\delta$ are multiple arcs, we define the geometrical intersection numbers of $\gamma$ and $\delta$ to be the minimum of $\text{card}(c \cap d)$, where $c$ and $d$ vary among the essential one-submanifolds of $F$ representing $\gamma$ and $\delta$. The result from [8] just
mentioned suggests that the geometrical intersection numbers of a multiple arc with the (isotopy class of) each of the boundary components \( \partial_k \) of \( P \) are useful in parametrizing multiple arcs in \( P \). Note that if \( c \) is a properly embedded one-submanifold in \( P \), and \( m_k = \text{card}(c \cap \partial_k) \), then \( m_1 + m_2 + m_3 \) is even.

Given any triple \( m_1, m_2, m_3 \) of non-negative integers with \( m_1 + m_2 + m_3 \) even, we now construct a multiple arc attaining the intersection numbers \( m_1, m_2 \) and \( m_3 \) and meeting \( \partial_k \) in \( w_k \) (if at all).

**Construction 2.1:** Let \( \ell_{ij} \) denote the arc in the standard pair of pants indicated in Figure 2.3, for \( 1 \leq j = 1, 2, 3 \). Note that \( \ell_{ij} \) connects boundary components \( \partial_i \) and \( \partial_j \) of \( P \). We call an arc parallel to some \( \ell_{ij} \) a canonical piece. Note that by definition of parallelism for arcs in the standard pair of pants, the endpoints of an arc parallel to some \( \ell_{ij} \) always lie in the windows \( w_k \).

For each triple \( m_1, m_2, m_3 \) with \( m_1 + m_2 + m_3 \) even, we construct a one-submanifold of \( P \) with no boundary-parallel components, called a canonical model. We construct these canonical models by taking various disjointly embedded collections of the canonical pieces. There are four cases, as follows:

a) The \( m_i \) satisfy all possible triangle inequalities (that is, \( m_1 \leq m_2 + m_3 \), \( m_2 \leq m_1 + m_3 \) and \( m_3 \leq m_1 + m_2 \)). In this case, we take a disjointly embedded collection consisting of:

- \( (m_1 + m_2 - m_3)/2 \) mutually disjoint parallel copies of arc \( \ell_{12} \).
- \( (m_1 + m_3 - m_2)/2 \) mutually disjoint parallel copies of arc \( \ell_{13} \).
- \( (m_2 + m_3 - m_1)/2 \) mutually disjoint parallel copies of arc \( \ell_{23} \).

An example when \( m_1 = 3, m_2 = 1 \) and \( m_3 = 2 \) is given in Figure 2.4a.
b) $m_1 > m_2 + m_3$. In this case we take a disjointly embedded collection consisting of:

- $m_2$ mutually disjoint parallel copies of arc $l_{12}$.
- $m_3$ mutually disjoint parallel copies of arc $l_{13}$.
- $(m_1 - m_2 - m_3)/2$ mutually disjoint parallel copies of arc $l_{11}$.

An example when $m_1 = 4$, $m_2 = 1$ and $m_3 = 1$ is pictured in Figure 2.4b. The next two cases are similar to case b).

c) $m_2 > m_1 + m_3$. In this case we take a disjointly embedded collection consisting of:

- $m_1$ mutually disjoint parallel copies of arc $l_{12}$.
- $m_3$ mutually disjoint parallel copies of arc $l_{23}$.
- $(m_2 - m_1 - m_3)/2$ mutually disjoint parallel copies of arc $l_{22}$.

d) $m_3 > m_1 + m_2$. In this case we take a disjointly embedded collection consisting of:

- $m_2$ mutually disjoint parallel copies of arc $l_{23}$.
- $m_1$ mutually disjoint parallel copies of arc $l_{13}$.
- $(m_3 - m_1 - m_2)/2$ mutually disjoint parallel copies of arc $l_{33}$.

**Remark 2.1:** Let $\ell_{ij}(m_1, m_2, m_3)$ be the number of canonical pieces of type $l_{ij}$ in the canonical model described in Construction 2.1. By counting the number of times each canonical piece intersects the boundary curves $\partial_k$, one easily verifies that the following identities are valid in all cases of Construction 2.1.

- $m_1 = 2\ell_{11} + \ell_{12} + \ell_{13}$
- $m_2 = 2\ell_{22} + \ell_{12} + \ell_{13}$
- $m_3 = 2\ell_{33} + \ell_{13} + \ell_{23}$

**Remark 2.2:** It is easy to check that it is possible to choose such
disjointly embedded collections for each case, and moreover that all possible combinations of disjointly embedded canonical pieces are described by these four cases. For instance, $l_{11}$ and $l_{33}$ cannot be embedded disjointly, as is obvious geometrically. (It also follows immediately from the main theorem of Section 4.)

Figure 2.3
We next state and prove the main parametrization theorem; it is
due to Dehn [5] and Thurston [17] independently. Subsequently, we define
a different parametrization, which is the one we will use. The proof
that our description does give a parametrization will follow as a
corollary to the proof of the Dehn-Thurston theorem.

**Theorem 2.1 (Dehn-Thurston):** If \( F \) is a compact oriented surface with
pants decomposition \( \{K_i\}_{i=1}^N \), then there is a parametrization of \( \mathcal{P}(F) \)
by a subset of \( \mathbb{Z}^+ \times \mathbb{Z}^N \), where \( \mathbb{Z}^+ \) denotes the non-negative integers. The
point \( (m_1, \ldots, m_N) \times (t_1, \ldots, t_N) \in (\mathbb{Z}^+)^N \times \mathbb{Z}^N \) corresponds to a multiple arc
if and only if the following conditions are satisfied:

a) If \( m_i = 0 \), then \( t_i \geq 0 \).

b) If \( K_i, K_j \) and \( K_k \) bound an embedded pair of pants, then
\( m_i + m_j + m_k \) is even.

c) If \( K_i \) bounds an embedded torus-minus-a-disc, then \( m_i \) is even.

We call this parametrization the **Dehn-Thurston** parametrization; it
depends on certain choices which we now describe.
Let $A_i$ be a regular neighborhood of $K_i$ in the surface $F$. Choose a trivialization $\nu_i$ of $A_i$ as follows: it is an orientation-preserving homeomorphism which carries $A_i$ to the standard oriented annulus $A = S^1 \times [-1,1]$ if $K_i$ is in the interior of $F$, and carries $A_i$ to $S^1 \times [0,1] \subset S^1 \times [-1,1]$ if $K_i$ is a boundary component of $F$. Let $G$ be a projection of $A$ onto the core $S^1 \times 0 \subset A$. Note that $S^1 \times 0 = \nu_i(K_i)$ by definition of a trivialization. Choose an embedded arc $u_i \subset K_i$, called a window, let $D_j$ be the closure of a component of $F \setminus \bigcup \{A_i\}$, and choose an orientation-preserving homeomorphism $f_j$ of $D_j$ to $P$ carrying $(\nu_1^{-1} G^{-1} \nu_1(u_1)) \cap D_j$ to a window $w_1, w_2$ or $w_3$ in the standard pair of pants $P$.

In practice, we regard $F$ as embedded in $S^3$ and draw pictures. $\nu_i$ is chosen as the trivialization that extends across a disc in $S^3$ with boundary $K_i$, and $G$ is taken to be the projection along the fibers in the standard annulus $A$. We then draw and label $\{K_i\}, \{u_i\}, f_j^{-1}(1_{12})$ and $f_j^{-1}(1_{13})$ as in Figures 2.5 and 2.6. Since $P \setminus \{1_{12}, 1_{13}\}$ is contractible, some straightening and the Alexander Lemma show that $f_j^{-1}(1_{12})$ and $f_j^{-1}(1_{13})$ determine $f_j$ up to isotopy. For example, we let $f$ and $f'$ be the homeomorphism to the standard pants $P$ corresponding to the choices in Figures 2.6a and 2.6b, respectively. The map $f' \circ f^{-1}$ from $P$ to itself is isotopic to a right Dehn twist along the boundary component $\partial_3$ of $P$.

**Proof of Theorem 2.1:** We first describe how one computes the Dehn-Thurston parameter values for some $\gamma \in \mathcal{P}(F)$. Define the intersection numbers $m_i$ to be the geometrical intersection numbers of $\gamma$ with (the isotopy class of) $K_i$. Choosing a representative $c$ for $\gamma$, we may isotope $c$ to attain these intersection numbers with each component of $\partial A_i$ by [8, Proposition 3.12]. Thus, for any $i$, a component of $c \cap A_i$ intersects each component of $\partial A_i$. 
Isotope \( c \) so that it intersects each component of \( \partial A_i \) in \( v_1^{-1} \log^{-1} u_i(u_i) \) and so that \( f_j(c \cap D_j) \) is one of the canonical models in Construction 2.1. (This is possible by the result from [8] mentioned before Construction 2.1.) We then define the twisting numbers \( t_i \) as follows:

- If \( m_i = 0 \), take \( t_i \) to be the number of components of \( u_1(c \cap A_1) \).
- If \( m_i > 0 \), then \( |t_i| \) is defined to be the geometrical intersection
number of the isotopy class rel $\partial A_i$ of $u_i(c \cap A_i)$ and $G^{-1}(x)$, where $x$ is one of the boundary points of the window $u_i$. The sign of $t_i$ is positive if some component of $u_i(c \cap A_i)$ twists to the right in the oriented annulus $A$, and the sign of $t_i$ is negative if some component of $u_i(c \cap A_i)$ twists to the left in the oriented annulus $A$. (Note that if one component of $u_i(c \cap A_i)$ twists to the right, no component can twist to the left.)

It follows immediately from [8, Lemma 4.5] that at most one $\gamma \in \mathcal{P}(F)$ may achieve a particular tuple of intersection numbers and twisting numbers. One shows easily that every parameter value is achieved, using Construction 2.1. The theorem follows. $\Box$

**Example 2.1:** Consider the pants decomposition on the surface $F_2$ indicated in Figure 2.7. We will draw a representative $c$ of the multiple arc $\gamma$ with Dehn-Thurston parameter values $(3,1,2) \times (2,-1,0) = (m_1,m_2,m_3) \times (t_1,t_2,t_3)$. There are three components of $c \cap A_1$ since $m_1=3$, and two of these twist to the right since $t_1=+2$. (It is geometrically impossible to have one component twist around 2 times and the other not at all.) Similarly, there is one component of $c \cap A_2$ since $m_2=+1$, and it twists once to the left since $t_2=-1$; there are two components of $c \cap A_3$ since $m_3=2$ and no twisting since $t_3=0$. Thus, we draw our representative $c$ of $\gamma$ in each of the annuli $A_i$, $i=1,2,3$, as in Figure 2.8a. We then connect up these arcs uniquely using the pre-images (under $f_1$ and $f_2$) of canonical pieces parallel to $1_{12},1_{23},1_{13}$ as shown in Figure 2.8b.

**Example 2.2:** Continuing to use the choice of conventions indicated in Figure 2.7, we will draw a representative $c$ of the multiple arc $\gamma$ with Dehn-Thurston parameter values $(0,1,1) \times (2,-2,1) = (m_1,m_2,m_3) \times (t_1,t_2,t_3)$. There is one component of each of $c \cap A_2$ and $c \cap A_3$ since
m_2 = m_3 = 1. There are two twists to the left in A_2 and one to the right in A_3 since t_2 = -2 and t_3 = 1. Since m_1 = 0, c does not intersect A_1, and since t_1 = 2, there are two components in A_1 parallel to K_1. Again we draw our representative c of \gamma in each of the annuli A_i, i = 1,2,3, as in Figure 2.9a, and we connect up the arcs uniquely as in Figure 2.9b.
Remark 2.3: As indicated in the examples, sometimes a multiple arc has a connected representative and sometimes not. It is a hard combinatorial problem to compute the number of components of a multiple arc given only its Dehn-Thurston parameter values. Except for a few special cases, this remains an open problem.

We define a basis $A$ for multiple arcs to be a choice of pants decomposition together with a choice of conventions as in the proof of the Dehn-Thurston theorem, including a choice of (parallelism class of) canonical pieces for each embedded pair of pants $D_j$. Note that the Dehn-Thurston parametrization depends on a choice of basis, and that once a basis is chosen, there is a one-to-one correspondence between $\mathcal{P}(F)$ and the integral lattice described in Theorem 2.1.

The choice of parallelism class of canonical pieces of type $l_{12}$, $l_{13}$ or $l_{23}$ is determined by the choices in Construction 2.1. Consider our choice of canonical piece $l_{11}$ drawn in Figure 2.10a. The isotopy indicated in Figure 2.10 shows that the arc in Figure 2.11, denoted $\hat{l}_{11}$, corresponds to a different choice of parallelism class for the canonical piece $l_{11}$. Similar remarks apply to the canonical pieces $l_{22}$ and $l_{33}$, and we indicate some alternative choices, denoted $\hat{l}_{22}$ and $\hat{l}_{33}$, in Figure 2.11.

We will say that an essential one-submanifold $c$ is in good position with respect to a basis $A$ if $f_j(c \cap D_j)$ is a canonical model for each $j$; furthermore, for each $i$, we require that $c$ intersect a component of $\mathfrak{A}_i$ exactly $m_i$ times, where $m_i$ is an intersection number of the Dehn-Thurston parametrization.

Instead of keeping track of the intersection number $m_i$, one might keep track of the numbers $\ell_{**}^j$ of canonical pieces of a good representative
Figure 2.10

Figure 2.11
parallel to each \( l_{**} \) in each embedded pair of pants \( D_j \). This is the idea behind our parametrization of multiple arcs. The corresponding integral lattice with respect to the basis \( A \) will be denoted \( \mathcal{P}_A'(F) \).

**Corollary 2.1:** If \( F \) is a compact oriented surface with pants decomposition \( \{K_i\}_1^N \) into \( M \) embedded pairs of pants \( \{D_j\} \), then there is a parametrization of \( \mathcal{P}'(F) \) by a subset of \((\mathbb{Z}^+)^M \times \mathbb{Z}^N\). The subset is denoted \( \mathcal{P}'_A(F) \). To the multiple arc \( \gamma \), we associate the tuple

\[
\left( \ell_{11}^j, \ell_{12}^j, \ell_{13}^j, \ell_{22}^j, \ell_{23}^j, \ell_{33}^j \right) \times (t_1, \ldots, t_N) \in (\mathbb{Z}^+)^M \times \mathbb{Z}^N.
\]

The \( t_j \) are the twisting numbers in the Dehn-Thurston parametrization, and the number \( \ell_{**}^j \) denotes the number of components of \( f_j \circ c \) parallel to the canonical piece \( l_{**} \), where \( c \) is a good representative of \( \gamma \) with respect to the basis \( A \). The corresponding subset \( \mathcal{P}'_A(F) \) satisfies the following conditions:

a) \( \ell_{12}^j \neq 0 \) implies \( \ell_{33}^j = 0 \), for all \( j \).

b) \( \ell_{13}^j \neq 0 \) implies \( \ell_{22}^j = 0 \), for all \( j \).

c) \( \ell_{23}^j \neq 0 \) implies \( \ell_{11}^j = 0 \), for all \( j \).

d) \( \ell_{11}^j \neq 0 \) implies \( \ell_{23}^j = \ell_{12}^j = \ell_{33}^j = 0 \), for all \( j \).

e) \( \ell_{22}^j \neq 0 \) implies \( \ell_{13}^j = \ell_{11}^j = \ell_{33}^j = 0 \), for all \( j \).

f) \( \ell_{33}^j \neq 0 \) implies \( \ell_{12}^j = \ell_{11}^j = \ell_{22}^j = 0 \), for all \( j \).

g) If \( K_i \) is isotopic to both \( f_j^{-1}a_1 \) and \( f_j^{-1}a_2 \), then \( \ell_{11}^j = \ell_{22}^j = 0 \).

h) If \( K_i \) is isotopic to both \( f_j^{-1}a_2 \) and \( f_j^{-1}a_3 \), then \( \ell_{22}^j = \ell_{33}^j = 0 \).

i) If \( K_i \) is isotopic to both \( f_j^{-1}a_1 \) and \( f_j^{-1}a_3 \), then \( \ell_{11}^j = \ell_{33}^j = 0 \).

If \( K_i \) is isotopic to \( f_j^{-1}a_k \), we define

\[
m(K_i,j) = \begin{cases} 
2\ell_{11}^j + \ell_{12}^j + \ell_{13}^j, & k=1, \\
2\ell_{22}^j + \ell_{12}^j + \ell_{23}^j, & k=2, \\
2\ell_{33}^j + \ell_{13}^j + \ell_{23}^j, & k=3.
\end{cases}
\]
We further require that

j) \( m(K_i, j) = 0 \) implies that \( t_i > 0 \).

k) If \( K_i \) is isotopic to both \( f_{j_1}^{-1} \beta_k \) and \( f_{j_2}^{-1} \beta_k' \), then \( m(K_i, j) = m(K_i, j') \), \( j = j' \).

Proof: Restriction a)-f) follow from Remark 2.2. Restriction j) is
convention a) of Theorem 2.1, and restriction k) guarantees that the
pants glue together properly. Restrictions g)-i) require further
comment. Suppose that \( K_i \) is isotopic to both \( f_{j_1}^{-1} \beta_1 \) and \( f_{j_2}^{-1} \beta_2 \); suppose,
moreover, \( f_{j_2}^{-1} \beta_3 \) is isotopic to \( K_i' \). Since \( f_{j_1}^{-1} \beta_1 \) and \( f_{j_2}^{-1} \beta_2 \) are isotopic,
geometric intersection numbers with these curves are the same for all
multiple arcs in \( F \). Thus, either \( m_{i_1} < 2m_1 \) or \( m_{i_1} > 2m_1 \), and we are in
case a) or d) of Construction 2.1, in which case \( \ell_{11} = 0 \) and \( \ell_{22} = 0 \).

An example where \( m_{i_1} = 4 \) and \( m_1 = 1 \) is indicated in Figure 2.12a, and
an example when \( m_{i_1} = 2 \) and \( m_1 = 1 \) is indicated in Figure 2.12b. Restrictions
h) and i) are analogous.

Figure 2.12
Thus, these restrictions are all necessary. Sufficiency follows by applying Construction 2.1 to give examples for each parameter value satisfying a)-k). The corollary follows.

To be sure, this parametrization is less algebraically clean than the Dehn-Thurston parametrization, but it is geometrically natural and is what we need. In fact, we have embedded the integral lattice of the Dehn-Thurston parametrization in a large-dimensional integral lattice. Note moreover that by the formulas of Remark 2.1 and Construction 2.1, one can pass back and forth between the Dehn-Thurston parametrization and our own parametrization, provided that both are computed relative to the same basis $A$. We introduce the second parametrization because the action of $\text{MC}(F_g)$ on $\mathcal{P}'(F_g)$ is simpler than its action on the Dehn-Thurston integral lattice, as we shall see.

In subsequent sections, we will compute the action of $\text{MC}(F_g)$ on the collection of multiple arcs in $F_g$. Corollary 2.1 tells us that given a choice of basis $A$, there is a one-to-one correspondence between the set $\mathcal{P}'(F_g)$ and the subset $\mathcal{P}'_A(F_g)$ of $\mathbb{Z}^{15g-15}$. Thus, after a choice of basis $A$, we may describe the action of $\text{MC}(F_g)$ on $\mathcal{P}'(F_g)$ in coordinates: we compute the corresponding action on the particular integral lattice $\mathcal{P}'_A(F_g)$.

**Remark 2.4:** In the sequel, we will regard $\mathcal{P}_A(F) \subset (\mathbb{Z}^+)^{6M} \times \mathbb{Z}^N$, and we will regard $\{t_{\alpha}^j, t_1\}$ as a collection of generators for $\mathcal{P}'(F)$ satisfying certain relations. Thus, if $\gamma$ and $\delta$ are multiple arcs, we may speak of the sum of their corresponding parameter values. If $\gamma$ and $\delta$ have disjointly embedded representatives, then the sum of their parameter values corresponds to the isotopy class of the union of these representatives.
If $\gamma$ and $\delta$ do not have disjointly embedded representatives, then the sum of their parameter values may or may not correspond to some multiple arc, depending on whether restrictions a)-f) of Corollary 2.1 are satisfied for this sum.

The reader wishing to familiarize him or herself with the parametrizations is urged to consult Figures 3.8 and 7.4 for definitions of bases and then verify the computations in Appendix B.

Without too much trouble, one can extend the results of this section to a non-compact and/or non-orientable surface $F$ with negative Euler characteristic and two-sided essential one-submanifolds embedded in $F$. For our present purposes, it is not worth the effort.
SECTION 3

In the previous section, we gave an explicit parametrization relative to a basis $A$ for the collection of multiple arcs in the $g$-holed torus by an integral lattice $\mathcal{P}_A(F_g) \subset \mathbb{Z}^{15g-15}$. Our main goal is to compute the action of $MC(F_g)$ on $\mathcal{P}(F_g)$ by computing its action in coordinates on the particular integral lattice $\mathcal{P}_A(F_g)$. The specification of an element of $MC(F_g)$ depends on a result of Lickorish [11] which gives a collection of generators for $MC(F_g)$ provided $g \geq 2$.

Just as Dehn knew of a parametrization for multiple arcs, he also constructed a finite set of generators for $MC(F_g)$ [6] called Dehn twists, whose definition we will recall presently. Lickorish independently refined this result by exhibiting a more useful collection of $3g-1$ Dehn twist generators for $MC(F_g)$. More recently, S. Humphries [10] has sharpened this result. In his thesis, Humphries gives a collection of $2g+1$ Dehn twist generators for $MC(F_g)$ and shows that $2g+1$ is the least possible number of such. (Humphries' generators are contained in Lickorish's set.)

A Dehn twist along a curve $c$ in an oriented surface $F$ is defined as follows. We identify a closed regular neighborhood $N$ of $c$ with the standard oriented annulus $A = S^1 \times [-1,1]$ via an orientation-preserving homeomorphism $f_c$. On the neighborhood $N$ of $c$, define the right and left Dehn twists on $c$, denoted $\tau^+_c$ and $\tau^-_c$, to be the conjugate by $f_c$ of the map $(\Theta, t) \rightarrow (\Theta \pi(t+1), t)$ on the standard annulus $A$; define $\tau^+_c$ to be the identity on $F \setminus N$. This construction is independent of the orientation of $c$, and the mapping class of $\tau^+_c$ depends only on the isotopy class of the unoriented curve $c$ and the orientation of $F$. 
Figure 3.1 illustrates the curves $\tau_c^{\pm 1}d$, where $c$ and $d$ are as pictured. The action of a single Dehn twist on a connected element of $\mathcal{P}_A(F_g)$ can be quite complicated. A reasonably complicated example of such an action is indicated in Figure 3.2.
A fundamental theorem in the study of surfaces is the theorem of Lickorish mentioned previously.

**Theorem 3.1 (Lickorish):** If \( \mathcal{L}_g \) is the collection of \( 3g-1 \) curves on the \( g \)-holed torus pictured in Figure 3.3, then \( \text{MC}(F_g) \) is generated by the Dehn twists along the elements of \( \mathcal{L}_g \).

![Figure 3.3](image)

It follows that \( \text{MC}(F_g) \) is a quotient of the free group on Lickorish's generators, and a precise statement of our main problem is:

**Problem:** For some choice of basis \( A \) for \( \mathcal{P}(F_g) \), compute the action on \( \mathcal{P}(F_g) \) of Dehn twists along the curves in \( \mathcal{L}_g \).

Provided that \( F_g \) is oriented and regarded as embedded in \( S^3 \), a basis \( A \) for the collection of multiple arcs is:

- a) A pants decomposition \( \{K_i\}_{i=1}^{N=3g-3} \) of \( F_g \), and a window \( u_i \subset K_i \) for each curve \( K_i \).
- b) A homeomorphism \( f_j : D_j \rightarrow P \) from each embedded pair of pants \( D_j \) (which is a component of \( F_g \setminus \{ A_i \} \), where \( A_i \) is a regular neighborhood of \( K_i \)) to the standard pants \( P \).
c) A choice of canonical pieces (as in Construction 2.1) for each embedded pair of pants $D_j$.

Fix some basis $A$ for now, and suppose that we want to compute the action on the Dehn-Thurston parametrization for multiple arcs of $\tau_{K_k}^{\pm 1}$, the Dehn twists on the pants curve $K_k$ of the basis $A$. If $\gamma$ is a multiple arc with Dehn-Thurston parameters $\{(m_i, t_i)\}_{i=1}^N$, then $\tau_{K_k}^{\pm 1}\gamma$ has Dehn-Thurston parameter values $\{(m_1, t_1), \ldots, (m_{k-1}, t_{k-1}), (m_k, t_k), \ldots, (m_{k+1}, t_{k+1}), \ldots, (m_N, t_N)\}$. Note that this result is independent of choices b) and c) above.

Example 3.1: Adopting the basis $A$ on $F_2$ indicated in Figure 2.7, we compute the action of the word $\tau_{K_1}^2 \tau_{K_2}^2 \tau_{K_3}^2$ on the multiple curve with corresponding Dehn-Thurston parameter values $\{(3,1,2), (2,-1,0)\}$. (We will read words in Lickorish's generators from right to left. Note, however, that $\tau_{K_1}^2, \tau_{K_2}^2$ and $\tau_{K_3}^2$ commute with one another since the curves $K_1$ are all disjoint.) Let $c$ be the good representative of $\gamma$ shown in Figure 2.8b. By isotopy, one can arrange that $\tau_{K_1}^2$ is the identity off the annular neighborhood $A_1$ of $K_1$ used in the basis $A$. Thus, the image of $c$ under $\tau_{K_1}^2 \tau_{K_2}^2 \tau_{K_3}^2$ agrees with $c$ outside of $\{A_1\}$, and $\tau_{K_1}^2 \tau_{K_2}^2 \tau_{K_3}^2 c$ is a good representative of its isotopy class with respect to the basis $A$. This curve is pictured in Figure 3.4 and has Dehn-Thurston parameter values $\{(3,1,2), (5,1,2)\}$ relative to the basis $A$.

Similarly simple (but more awkward to state) is the action of $\tau_{K_k}^{\pm 1}$ on the integral lattice $\mathcal{L}_A(F_g)$, where $K_k$ is a pants curve in the basis $A$. It would thus serve us well to choose a pants decomposition for $F_g$ that overlaps as much as possible with the Lickorish curves $\mathcal{L}_g$. 
For $F \subset S^3$, we choose the standard pants decomposition and the standard homeomorphisms $f_j : D_j \to P$ indicated in Figure 3.5. For the time being, we make choice c) above as in Construction 2.1. As one might expect, these choices give the standard basis $A_g$ on $F_g$. 

Figure 3.4

For $F \subset S^3$, we choose the standard pants decomposition and the standard homeomorphisms $f_j : D_j \to P$ indicated in Figure 3.5. For the time being, we make choice c) above as in Construction 2.1. As one might expect, these choices give the standard basis $A_g$ on $F_g$. 

Figure 3.5
Let \( \mathcal{L}_g \) be the collection of \( 2g-1 \) curves in \( F_g \) indicated in Figure 3.2. The Lickorish curves \( \mathcal{L}_g \) are contained in \( \mathcal{C}_g \cup \{K_1\}^{3g-3} \). Thus, to solve the main problem, it remains to analyze the twists \( \tau_{c}^{\pm 1} \), for \( c \in \mathcal{C}_g \). Note that in fact the containment \( \mathcal{L}_g \subset \mathcal{C}_g \cup \{K_1\}^{3g-3} \) is proper.

Consider the various changes of basis indicated in Figure 3.7 (preserving the choice \( c \)) of canonical pieces). This picture shows that for each curve \( c \in \mathcal{C}_g \), there is a change of basis \( A_g \rightarrow B \) so that \( c \) is a pants curve in the basis \( B \). Conjugating by this change of basis, we could thus compute as above the action of \( \tau_{c}^{\pm 1} \) on \( \mathcal{P}_A(F_g) \) for \( c \in \mathcal{C}_g \). The philosophy comes from linear algebra: if a transformation \( (\tau_{c}^{\pm 1} \) for \( c \in \mathcal{C}_g \)) is hard to compute, change basis.

Note that in fact computing these changes of basis will allow us to compute the action on \( \mathcal{P}_A(F_g) \) of Dehn twists not only along
Figure 3.7 (genus=2)
Figure 3.7 (g > 3)
the 3g-1 curves in \( \mathcal{C}_g \), but along all 5g-4 curves in \( \mathcal{C}_g \cup \{K_1 \}^{3g-3} \).

Though the action of the Humphries Dehn twist generators alone would suffice to describe the action of \( \text{MC}(F_g) \) on multiple arcs, we use this much larger set for two reasons: we get the extra information for free, and the greater number of generators allows a greater flexibility in specifying mapping classes. Moreover, I do not know of a way to take advantage of considering only the Humphries generators.

Each change of basis in Figure 3.7 can be written as a composition of the elementary transformations pictured in Figure 3.8. We have thus reduced the main problem to the computation of the two elementary transformations. This reduction of the problem was shown to me by Gabai [9].

![Diagram](image)

The first elementary transformation is comparatively simple, and the computations can be done by hand (by actually isotoping curves
and arcs about on the torus-minus-a-disc), but the second elementary transformation requires some work. However, the machinery we develop to handle the second elementary transformation also applies to the first elementary transformation. We next describe some of this machinery and outline the actual computations.

Let $S_1$ be the torus-minus-a-disc, and let $S_2$ be the sphere-minus-four-discs. Let $A$ be the basis on $S_1$ indicated in Figure 3.8a, and let $A'$ be the basis on $S_1$ indicated in Figure 3.8b, $i=1,2$. Given a multiple arc $\gamma$, we choose a good representative $c$ of $\gamma$ with respect to the basis $A$, and we orient the components of $c$ arbitrarily. We will choose a lift $\tilde{c}$ of $c$ to a certain regular planar cover $\tilde{\Pi}_i: \tilde{S}_i \to S_i$. We isotope $\tilde{c}$ about in $\tilde{S}_i$ to some $\tilde{c}$ so that each component of $f_j(\tilde{\Pi}_i \tilde{c}, D_j)$ is a canonical piece in the standard pants $P$, where the $f_j$ are the homeomorphisms of the basis $A$. Define $\overline{c} = \tilde{\Pi}_i \tilde{c}$. The reason for passing to a covering space is that we gain a facility in picturing the homotopy from $c$ to $\overline{c}$ as an isotopy from $\tilde{c}$ to $\tilde{c}$. However, we cannot guarantee that the isotopy from $\tilde{c}$ to $\tilde{c}$ is $\tilde{\Pi}_i$-equivariant, so $\overline{c}$ is not in general embedded. However, $\overline{c}$ is at least homotopic to the embedding $c$.

We will introduce a combinatorial object, called a symbol, in Section 5. The collection of symbols relative to a basis $A$ forms a semi-group, and we associate to each tuple in $\mathcal{P}_A(S_1)$ some symbol. More generally, we will associate a symbol to an immersed one-submanifold such as $\overline{c}$.

It turns out that the symbol of $\overline{c}$ is the symbol of an embedding $c'$ homotopic to $\overline{c}$. $c$ and $c'$ are thus homotopic, and, in fact, $c'$ will be in good position with respect to the basis $A'$. It is well known [7]
that two homotopic embedded one-submanifolds are in fact isotopic. 
(This also follows from the results of the next section.) $c'$ is thus 
a good representative of $\gamma$ with respect to the basis $A'$, and we can 
compute the parameter value of $\gamma$ in $\mathcal{P}_{A'}(S_1)$ from the symbol of $c'$
(which is the same as the symbol for $\overline{c}$). Thus, the elementary 
transformations are given by maps between semi-groups of symbols, which 
we will call combinatorial homotopies.

The difficult part of this process is showing that the symbol of $\overline{c}$ is in fact the symbol of an embedding $c'$ homotopic to $\overline{c}$. We prove 
some results about one-submanifolds immersed in surfaces in the next 
section that are of independent interest. These are applied in Section 
5 to show that if the symbol of $\overline{c}$ satisfies a few technical properties, 
then such a $c'$ exists. Much of the hard combinatorial work of Sections 
6 and 7, where we compute the two elementary transformations in turn, 
is devoted to showing that the particular symbol for $\overline{c}$ satisfies these 
technical properties.

The planar covers $\Pi_i:S_i \rightarrow S_1$, $i=1,2$, are defined in Sections 6 and 
7. They are particularly pleasant to work with. The two groups of 
covering translations are groups of isometries of $\mathbb{R}^2$ with its usual 
metric. Thus, the push-forward under $\Pi_i$ of the usual metric on $S_i \subset \mathbb{R}^2$ 
gives a Euclidean structure on $S_1$. For the special case of multiple 
curves with no boundary-parallel components, the combinatorial 
homotopies that describe the elementary transformations are closely 
related to straightening to geodesics in this Euclidean structure.

The reader wishing to skip the explicit computations can proceed 
directly to Section 8, where we give the formulae for the elementary 
transformations and discuss some applications.
As usual, though we restrict attention to the case of g-holed tori, the techniques described in this section work for an arbitrary non-compact and/or non-orientable surface \( F \) of negative Euler characteristic. In case \( F \) is non-orientable, we interpret \( \text{MC}(F) \) as the group generated by isotopy classes of Dehn twists. (It is not true that the Dehn twists generate the group of homeomorphisms of \( F \) modulo isotopy. See [1] and [12].) If \( F \) is non-orientable, we interpret \( \mathcal{P}'(F) \) as the collection of isotopy classes of two-sided essential one-submanifolds embedded in \( F \). With these more general definitions, the action of \( \text{MC}(F) \) on \( \mathcal{P}'(F) \) can always be computed from the two elementary transformations, as in this section.

A final observation: Thurston and Hatcher [19] have shown that one can pass between any two pants decompositions on \( F \) by sequences of our two elementary transformations.
In this section, we prove some results about one-manifolds properly immersed in surfaces. For convenience, we will assume that the surfaces we consider have a fixed smooth structure. As usual, we will also assume that our surfaces have a negative Euler characteristic.

Let \( j \) be a proper immersion of a (smooth) one-manifold in the surface \( F \). We will consider the image of \( j \) as an immersed manifold \( \alpha \), yet we will refer to the image under \( j \) of components of \( \partial \) as the "components" of \( \alpha \). We will also refer to a component of \( \alpha \) as a "closed component" or "arc component", according to whether the corresponding component of \( \partial \) is a circle or an arc. A specific choice of map \( j \) will be called a "parametrization" of the immersion \( \alpha \).

By an \( n \)-gon in \( F \) we mean a (smoothly) embedded open disc (whose closure lies in the interior of \( F \)) with embedded piecewise-smooth boundary and \( n \) discontinuities in the tangent of the bounding curve. Some examples of \( n \)-gons are pictured in Figure 4.1. If there is an \( n \)-gon in \( F \) with its frontier in an immersion \( \alpha \), then we say that \( \alpha \) has a complementary \( n \)-gon.

\[ \begin{align*}
\text{null-gon} & \quad \text{mono-gon} & \quad \text{bi-gon} & \quad \text{tri-gon}
\end{align*} \]

Figure 4.1
If \( \alpha \) has a complementary mono-gon or bi-gon, then the homotopies indicated in Figure 4.2 show that \( \alpha \) cannot have minimal self-intersection number in its homotopy class rel \( \partial F \). The main result of this section is a converse: if \( \alpha \) does not have minimal self-intersection number in its homotopy class rel \( \partial F \), then the application of a finite sequence of the homotopies indicated in Figure 4.2 gives a representative of the homotopy class of \( \alpha \) that does.

Figure 4.2

A special case (Corollary 4.1) of this result is applied in a rather technical setting in the next section. More generally, this result is useful for determining whether the homotopy class of a given immersion has an embedded representative: remove complementary mono-gons and bi-gons using the homotopies in Figure 4.2. This process terminates and either yields the desired embedding or an immersion with no complementary mono-gons or bi-gons, in which case there can be no embedded representative of the given homotopy class.
If $F$ is a surface of negative Euler characteristic, then it is well known [13] that $F$ supports a Riemannian metric of finite area and of constant $-1$ curvature so that $\tilde{F}$ is geodesic. The total space of a universal cover $\tilde{\Pi}: \tilde{F} \to F$ is isometric to a contractible subset of the Poincare disc $D$ with geodesic boundary. There is a natural compactification of the (open) Poincare disc by a circle, and the points in this circle, which is denoted $S^1_\infty$, are called the points at infinity. We regard $D < D \cup S^1_\infty$, which is homeomorphic to a closed disc, and regard the points at infinity as being infinitely far from any point in $D$. The closure of $\tilde{F}$ in $D \cup S^1_\infty$ is topologically a closed disc, which we will denote by $K$, and $K \cap S^1_\infty$ is called the limit set. The limit set is either all of $S^1_\infty$ or a Cantor set in $S^1_\infty$, depending on whether the surface $F$ is closed or has boundary. We denote by $\partial K$ the frontier of $K$ in $D$ plus the limit set, so that $\partial K$ is homeomorphic to a circle.

In the 1920's through 1940's, J. Nielsen developed a very beautiful theory of surface automorphisms [13] by studying the natural action of homeomorphisms of the surface on the points of $K$ at infinity. (In fact, Nielsen's work anticipates some of the recent developments in the theory of surface automorphisms. Nielsen had a pretty complete picture of current work in surface automorphisms, but he did not use the machinery of foliations, which had not yet been invented.) We will require in the sequel only a handful of elementary results from the Nielsen theory. We presently recall these facts. We may identify the group $\pi_1(F)$ of covering transformations with a discrete subgroup of the group of isometries of $D$, so that the subgroup consists entirely of hyperbolic Mobius transformations of $D$. A hyperbolic transformation
of \( D \) has a simple geometrical picture: geodesics in \( D \) are circles orthogonal to \( S^1_\infty \), and a hyperbolic transformation \( \psi \) is translation along such a geodesic. The fundamental points of \( \psi \) are the endpoints at infinity of this geodesic, called the axis of \( \psi \). The action of \( \psi \) on \( F \) extends continuously to an action on \( K \), and the fundamental points of \( \psi \) are the only fixed points of \( \psi \) on \( \partial K \). Finally, if two axes of elements of \( \pi_1(F) \) intersect at infinity, then they coincide, since otherwise their commutator would be a parabolic transformation \([14]\).

(Recall that \( \pi_1(F) \) consists entirely of hyperbolic transformations.)

Given a component \( c \) of the immersion \( \alpha \), we define a complete lift of \( c \) to \( K \), denoted \( \tilde{c} \), as follows. If \( c \) is a properly immersed arc or inessentially immersed closed curve, we define \( \tilde{c} \) to be simply a lift of \( c \) to \( F \subset K \). If \( c \) is an essentially immersed closed curve, we define \( \tilde{c} \) to be the closure in \( K \) of a bi-infinite sequence \( \{ \tilde{c}_i \} \) of lifts of \( c \) to \( F \subset K \), where the final point of \( \tilde{c}_i \) is the initial point of \( \tilde{c}_{i+1} \).

Thus, a complete lift of an essential curve component or proper arc component of \( \alpha \) is an arc properly immersed in the ball \( K \). A complete lift of an inessential closed curve component of \( \alpha \) is an immersed closed curve in \( F \subset K \).

We will consider only properly immersed one-submanifolds \( \alpha \) in general position in \( F \). We assume that \( \alpha \cap \partial F \) is already in general position in \( F \). Thus, \( \alpha \) has at most double points, and \( \alpha \) is embedded near \( \partial F \). Let \( \Delta(\alpha) \) denote the set of double points of \( \alpha \).

**Lemma 4.1:** Suppose that \( \alpha \) is a (smooth) one-submanifold properly immersed in a surface \( F \) in general position. \( \alpha \) has minimal self-intersection number in its homotopy class rel \( \partial F \) if and only if for every pair \( c \) and \( d \) of components of \( \alpha \) (with perhaps \( c = d \)), complete lifts
and \( \tilde{d} \) are embedded and satisfy one of

a) \( \tilde{c} \cap \tilde{d} = \varnothing \).

b) \( \tilde{c} \) and \( \tilde{d} \) intersect transversely in a point.

c) \( \tilde{c} \cap \tilde{d} = (\tilde{c} \cap \partial \Omega) \cap (\tilde{d} \cap \partial \Omega) \). (This implies that \( c \) and \( d \) are closed curve components of \( \alpha \) with homotopic powers, provided \( \tilde{c} \cap \tilde{d} \neq \varnothing \).)

d) \( \tilde{c} = \tilde{d} \). (This implies that \( c \) and \( d \) have homotopic powers.)

**Proof:** \( (\Leftarrow) \) We begin by counting the double point set of \( \alpha \) in case every complete lift of a component of \( \alpha \) is embedded. Choose, once and for all, lifts \( \tilde{c} \subset \tilde{F} \subset \tilde{K} \) of the components of \( \alpha \). Since \( \alpha \) is in general position in \( F \), we may choose our lift \( \tilde{c} \) starting at a point in \( c \setminus \Delta(\alpha) \).

Since \( \pi_1(F) \) act transitively on the fibers of \( \Pi \), if \( \tilde{p} \in \tilde{c} \cap \tilde{\Delta}(\alpha) \), there is some \( \tilde{p} \in \tilde{c} \cap \Pi^{-1}(p) \) and some complete lift \( \tilde{d} \) of some component \( d \) of \( \alpha \) with \( \tilde{p} \) in \( \tilde{d} \), and so that \( \tilde{c} \) is not contained in \( \tilde{d} \) (since \( \alpha \) is in general position). There is thus a one-to-one correspondence between \( c \setminus \Delta(\alpha) \) and the complete lifts of components of \( \alpha \) that intersect \( \tilde{c} \). Let \( N_c(\alpha) \) denote the cardinality of \( c \setminus \Delta(\alpha) \), so that

\[
\text{card } \Delta(\alpha) = \sum_{c \subset \alpha} N_c(\alpha).
\]

It is easy to show that any homotopy in \( F \) of \( \alpha \) rel \( \partial F \) lifts to \( \tilde{F} \) and extends continuously to a homotopy in \( K \) that is constant on \( \partial K \). Thus, if complete lifts are embedded and satisfy one of a)–d), then a homotopy in \( F \) of \( \alpha \) rel \( \partial F \) cannot decrease \( N_c(\alpha) \) for any component \( c \) of \( \alpha \), and the implication follows.

\( (\Rightarrow) \) We first show that complete lifts are embedded. To derive a contradiction, suppose that \( \tilde{c} \) is not embedded, where \( c \) is an arc or curve component of \( \alpha \). Parametrizing \( \tilde{c} \) (by the circle or interval), this means that there are parameter values \( t_1 < t_2 \) with \( \tilde{c}(t_1) = \tilde{c}(t_2) \).

Since \( \tilde{c} \) is either an arc or a closed curve properly immersed in the
disc $K$, $\tilde{c}[t_1,t_2]$ is null homotopic in $K$. Let $p = \tilde{c}(t_1) = \tilde{c}(t_2)$, so that $p$ is a double point $p$ of $c$. If $c$ is an arc component of $\alpha$, then $p$ is in the interior of $K$ by general position. If $c$ is an inessential curve component of $\alpha$, then $p$ is in the interior of $K$ since $\tilde{c}$ is. If $c$ is an essential curve component of $\alpha$, then since $\tilde{c}$ has distinct endpoints at infinity, $p$ is in the interior of $K$. Thus, $p$ has a neighborhood in the interior of $F$ as in Figure 4.3a, which we modify as in Figure 4.3b. The dotted lines in Figure 4.3 denote arcs immersed in $F$, and the mono-gon in Figure 4.3a denotes a disc immersed in $F$. This move decreases card $\Delta(\alpha)$ by exactly one, and it is the projection by $\Pi$ of a homotopy in $K$. This contradicts the minimality of $\alpha$ and proves that complete lifts are embedded.

![Figure 4.3](image)

Suppose that $c$ is an inessential curve component of $\alpha$, where $\alpha$ is in minimal position. Any complete lift $\tilde{c}$ must satisfy either a) or d) for any complete lift $\tilde{d}$ of any component $d$ of $\alpha$. This is because
one can easily homotope these inessential components to embedded circles out of the way. Thus, we may assume that \( \alpha \) has no inessential closed curve components.

Now, if \( c \) and \( d \) are components of \( \alpha \), and \( \tilde{c} \) and \( \tilde{d} \) have distinct endpoints yet fail to satisfy a), b) or d), then there are parameterizations of \( \tilde{c} \) and \( \tilde{d} \) (by the unit interval), and there are parameter values \( s_1 < s_2 \) and \( t_1 < t_2 \) with \( \tilde{c}(s_i) = \tilde{d}(t_i) \), \( i = 1,2 \). Moreover, \( c[s_1,s_2] * d^{-1}[t_1,t_2] \) must bound a disc in \( \tilde{F} \), where \( * \) denotes concatenation of arcs. Let \( \tilde{p} = \tilde{c}(s_1) = \tilde{d}(t_1) \) and \( \tilde{q} = \tilde{c}(s_2) = \tilde{d}(t_2) \), and let \( p = \tilde{p} \) and \( q = \tilde{q} \). If \( p \) and \( q \) are distinct double points of \( \alpha \), then there are neighborhoods of \( p \) and \( q \) in \( F \) as in Figure 4.4a, which we can modify as in Figure 4.4b, contradicting the minimality of \( \alpha \).

If \( p = q \), then by general position, either \( c = d \) is an arc component of \( \alpha \), or \( \tilde{c}[s_1,s_2] \) multiply covers the closed curve component
c and $\tilde{d}(t_1, t_2)$ multiply covers the closed curve component $d$.

In case $c = d$ is an arc component, general position implies that there is a covering translation $\psi \in \pi_1(F)$ carrying $\tilde{c}[s_1, s_2]$ to $\tilde{d}[t_1, t_2]$, and $\psi$ must interchange $p$ and $q$ since it acts without fixed points on $F$. Thus, $1 = \Pi(\tilde{c}[s_1, s_2] \times \tilde{d}^{-1}[t_1, t_2]) = (\Pi \tilde{c}[s_1, s_2])^2 \in \pi_1(F, p)$. Since $\pi_1(F, p)$ is without torsion, the loop $\Pi \tilde{c}[s_1, s_2]$ must be inessential, which is absurd because $\tilde{c}[s_1, s_2]$ is not a closed loop.

Suppose that $\tilde{c}[s_1, s_2]$ multiply covers the closed curve component $c$ and $\tilde{d}[t_1, t_2]$ multiply covers the closed curve component $d$. Since $p = q$, there is a covering transformation $\psi$ so that $\psi(p) = q$. Both $\psi(\tilde{d})$ and $\tilde{d}$ intersect $\tilde{c}$ at $q$; this violates the uniqueness of lifting unless $\psi(\tilde{d}) = \tilde{d}$. Thus, the fundamental points of $\psi$ coincide with the endpoints of $\tilde{d}$, and symmetrically for $\tilde{c}$. This contradicts the assumption that $\tilde{c}$ and $\tilde{d}$ have distinct endpoints at infinity.

Complete lifts of essential curve components have one endpoint in common if and only if both of their endpoints coincide. Thus, it remains to consider only the case of two essential closed curve components $c$ and $d$ so that $\tilde{c}$ and $\tilde{d}$ have the same endpoints at infinity. In this case, powers of $c$ and $d$ are easily shown to be homotopic, say $c^m = d^n$, where $|m| < |n|$. Consider the irregular cover of $F$ by an annulus $A$ corresponding to $\langle c^m \rangle = \pi_1(F, p)$, where $p$ is a point in $c \cap d$. (See [7],.) $c$ and $d$ each lift to closed curves in this cover that intersect. We may apply the move indicated in Figure 4.4 in the cover $A$ to reduce card $\Delta(a)$. This contradiction proves the lemma. $\Box$

If $c$ is connected and has a double point set $\Delta(c)$, we call $p \in \Delta(c)$ inessential if $c$ may be parametrized so that $c(s_1) = c(s_2) = p$, $s_1 < s_2$. 
where \( c[s_1, s_2] \) is null homotopic. We say \( p \neq q \in \Delta(c) \) are companions if either of conditions a) or b) below are satisfied.

a) There is a parametrization of \( c \) with \( p = c(s_1) = c(s_3) \) and 
\[ q = c(s_2) = c(s_4), \ s_1 < s_2 < s_3 < s_4, \]  
where \( c[s_1, s_2] * c^{-1}[s_3, s_4] \) is null homotopic.

b) There is a parametrization of \( c \) with \( p = c(s_1) = c(s_4) \) and 
\[ q = c(s_2) = c(s_3), \ s_1 < s_2 < s_3 < s_4, \]  
where \( c[s_1, s_2] * c[s_3, s_4] \) is null homotopic.

Figures 4.5a and 4.5b illustrate cases a) and b) of companion double points. If \( c \) and \( d \) are distinct and connected, we say \( p \neq q \in \Delta(c \cup d) \) are companions if there are parametrizations of \( c \) and \( d \) with \( p = c(s_1) = d(t_1) \) and \( q = c(s_2) = d(t_2), \ s_1 < s_2 \) and \( t_1 < t_2 \), where \( c[s_1, s_2] * d^{-1}[t_1, t_2] \) is null homotopic.

An immediate corollary of Lemma 4.1 is the following proposition.

**Proposition 4.1:** Suppose \( a \) is a properly immersed (smooth) one-submanifold in general position in a surface \( F \) with negative Euler characteristic.
Under these conditions, \( \alpha \) has non-minimal self-intersection number in its homotopy class rel \( \partial \mathcal{F} \) if and only if there is an inessential double point or there are a pair of companion double points in \( \alpha \).

The main result of this section is the following theorem.

**Theorem 4.1**: \( \alpha \) as above has non-minimal self-intersection number in its homotopy class rel \( \partial \mathcal{F} \) if and only if there is a mono-gon or a bi-gon with its boundary in \( \alpha \).

**Proof**: The implication \((\Leftarrow)\) is trivial as in Figure 4.2, and the implication \((\Rightarrow)\) takes some work to prove. To start off, suppose that \( \alpha \) is connected, and parametrize \( \alpha \) once and for all. Let \( \mathcal{J} \) be the collection of sub-intervals \([a,b]\) of the arc or curve which parametrizes \( \alpha \) so that one of the following three conditions is satisfied.

a) \( \alpha(a) = \alpha(b) \) is an inessential double point of \( \alpha \).

b) \( \alpha(a) = \alpha(b) \), and there is a companion \( q \) to \( \alpha(a) \) so that
\[
\alpha^{-1}(q) \subset [a,b].
\]

c) \( \alpha(a) \) and \( \alpha(b) \) are companion double points and \( \alpha^{-1}(\alpha(a)) \)
\[
\alpha^{-1}(\alpha(b)) \text{ are contained in } [a,b].
\]

By Proposition 4.1, \( \mathcal{J} \neq \emptyset \). Let \([a_0,b_0]\) be an innermost interval in \( \mathcal{J} \).

**Case a)**: \( \alpha(a_0) = \alpha(b_0) \) is inessential. If \( \alpha\big|_{(a_0,b_0)} \) is an embedding, we have exhibited the mono-gon bounded by \( \alpha[a_0,b_0] \). If \( \alpha\big|_{(a_0,b_0)} \) is not an embedding, then choose \( a_0 < a_1 < b_1 < b_0 \) so that \( \alpha(a_1) = \alpha(b_1) \) and so that \( \alpha\big|_{(a_1,b_1)} \) is an embedding. One can arrange this by choosing \([a_1,b_1]\) innermost among sub-intervals of \([a_0,b_0]\) so that \( \alpha(a_1) = \alpha(b_1) \). Let \( \beta = \alpha[a_1,b_1] \) and \( \gamma = \alpha^{-1}[a_0,a_1] \star \alpha^{-1}[b_0,b_1] \), so that \( \beta = \gamma \) as elements
of $\pi_1(F,\alpha(a_1))$. We modify $\beta$ and $\gamma$ in a neighborhood of $\alpha(a_1)$ as in Figure 4.6, and we retain the names $\beta$ and $\gamma^{-1}$ for the components of the result.

Now, $\gamma^{-1}$ is an immersion homotopic to the embedding $\beta^{-1}$, and so $\gamma^{-1}$ and $\beta$ are disjointly embedded since $[a_0, b_0]$ was chosen to be innermost, using Proposition 4.1. $\beta$ is not null homotopic since $[a_0, b_0]$ was chosen to be innermost, so $\gamma^{-1}$ and $\beta$ bound an annulus in $F$. Thus, $2\beta = 1$ in $\pi_1(F, \alpha(a_1))$, which is impossible.

In cases b) and c), if the innermost bi-gon is not embedded, then one easily constructs a null homotopic loop that is the composition of two disjointly embedded non null homotopic loops (consult Figure 4.5) and derives a contradiction as above.

This proves the theorem in case $\alpha$ is connected. In general, the same argument is valid provided $I$ also includes any intervals arising
from companions on different components of $\alpha$. 

**Corollary 4.1:** If $\alpha$ is a proper immersion homotopic to an embedding rel $3F$ and $\alpha$ is in general position in $F$, then either $\alpha$ is already embedded or there is a mono-gon or a bi-gon in $F$ with its boundary in $\alpha$. 

**Corollary 4.2:** If $\alpha$ and $\beta$ are proper immersions in general position each with minimal self-intersection number in its homotopy class rel $3F$, then $\alpha \cup \beta$ is in non-minimal position if and only if there is a bi-gon in $F$ with half its boundary in $\alpha$ and half its boundary in $\beta$. 

It is not true that if $\alpha$ and $\beta$ are proper immersions, then $\alpha \cup \beta$ is in non-minimal position if and only if there is a mono-gon or a bi-gon in $F$ with its boundary in $\alpha \cup \beta$ as the example pictured in Figure 4.7 indicates.

This section contains generalizations of some results of [7].

Corollary 4.2 is proved there for $\alpha$ and $\beta$ embedded curves.
This section contains a description of some of our technical foundations and a final overview of the computations to be performed in Sections 6 and 7. We will introduce a combinatorial description of curves and arcs immersed in surfaces, called symbols. We will then use the results of Section 4 to show that, under suitable conditions, a symbol for an immersed one-submanifold in fact describes an embedded one-submanifold. With this machinery developed, we distinguish four types of multiple arcs and give a detailed description of the computation of the two elementary transformations for each type. We then describe the computations of Sections 6 and 7 step by step.

Later in this section, when we apply the results of Section 4, we will require our surfaces to have a fixed smooth structure; for the present, we may work in the topological setting. We adopt the notation defined in Section 2, where we introduced the notion of a basis for the collection of multiple arcs. Fix a choice of basis $A$, let $M$ be the number of embedded pairs of pants $D_j$, and let $N$ be the number of curves $K_i$ for the basis $A$.

Suppose that $\alpha \in \mathcal{P}(F)$ is a multiple arc in the compact oriented surface $F$. We choose a good representative of $\alpha$ with components $\{c\}$, and we parametrize each component $c$ as a map from the unit interval or unit circle into $F$, depending on whether $c$ is an arc component or a closed curve component of $\alpha$. We have oriented the components of $\alpha$ arbitrarily and once and for all.

There is a finite partition of the unit interval or unit circle by intervals $[t_{k-1}, t_k]$, which is maximal subject to the condition
that $c(t_{k-1}, t_k)$ intersect $\bigcup_j \partial D_j$ exactly in $c(t_{k-1})$ and $c(t_k)$. Thus, each $c(t_{k-1}, t_k)$ is contained in either an annulus $A_i$ or an embedded pair of pants $D_j$. If $c(t_{k-1}, t_k) \subset A_i$, we formally associate to $[t_{k-1}, t_k]$ the symbol $s_{i}^{n}$, where $n$ is the twisting number of $u_i c(t_{k-1}, t_k)$ in the standard annulus $A_i$. $n$ is taken to be zero if $u_i c(t_{k-1}, t_k)$ runs directly from window to window with no twisting. If $c(t_{k-1}, t_k) \subset D_j$, we formally associate to $[t_{k-1}, t_k]$ the symbol $s_{11}^j, s_{12}^j, s_{13}^j, s_{22}^j, s_{23}^j$ or $s_{33}^j$, according to which canonical piece $l_{**}$ in the standard pants $f_j c(t_{k-1}, t_k)$ is parallel to. Each symbol in the following set is called a letter.

$$\{s_{i}^{n} : n \in \mathbb{Z}, i = 1, \ldots, N\} \cup \{s_{11}^j, s_{12}^j, s_{13}^j, s_{22}^j, s_{23}^j, s_{33}^j : j = 1, \ldots, M\}$$

Once the components of $a$ are oriented, it makes sense to distinguish between letters corresponding to canonical pieces with different orientations. It will be convenient to do this in Section 7; where we consider the second elementary transformation. For now, however, letters are to be regarded as "unoriented".

A connected symbol is defined to be an (ordered) sequence of letters. A symbol is defined to be a finite collection of connected symbols, called the components of the symbol. Once a basis $A$ is chosen we define the $A$-symbol of the component $c$ of $a$ to be the concatenation of the letters associated to $[t_{k-1}, t_k]$, in order. If $c$ is an arc component of $a$, then this symbol is unique (once $c$ is oriented); however, if $c$ is a closed curve component of $a$, the symbol depends on the choice of a starting point of the parametrization $c : S^1 \to F$ subject to $c(t_k) \in \bigcup_j \partial D_j$, for all $k$. Define the $A$-symbol of $a \in \mathcal{P}(F)$ to be the collection of symbols of components of $a$. We will call an $A$-symbol simply a symbol when the choice of basis is clear.
A symbol is thus a finite collection of words in the free semi-group on the letters. When convenient, we will use the semi-group notation. For instance, we will write the symbol \( (s^i \circ \circ s^1 \circ s^j \circ s^j')^n \) as shorthand for \( n \) concatenations of the symbol \( s^i \circ \circ s^1 \circ s^j \circ s^j' \). When convenient, we will also delete a letter \( s^0 \) from a symbol. For instance, we will write the symbol \( s^i \circ \circ s^1 \circ s^j \circ s^j' \) as shorthand for the symbol \( s^i \circ \circ s^1 \circ s^j \circ s^j' \).

We will say a symbol is embedded admissible (with respect to the basis \( A \)) if it arises as above from some multiple arc \( \alpha \). Embedded admissible symbols satisfy many properties. In Appendix A, we verify some simple properties of embedded admissible symbols. In particular, in Corollary A.1, we show that if \( s^{n_1} \) and \( s^{n_2} \) are letters in (some components of) an embedded admissible symbol, then \( \text{sgn}(n_1) = \text{sgn}(n_2) \). \( \text{sgn}(0) \) is undefined, but \( s^0 \) can occur only with \( s^+1 \) or \( s^-1 \). Any symbol satisfying this condition for each \( i=1, \ldots, N \) is said to be a constant parity symbol.

We will call a symbol immersed admissible (with respect to the basis \( A \)) if the following conditions are satisfied.

a) There is a (parametrized) immersion \( \tilde{\alpha} \) of a one-manifold \( 0 \) into \( F \) which is homotopic rel \( 3F \) to an embedding. \( \tilde{\alpha} \) may be either a proper or improper immersion.

b) There is a partition \( \{[t_{k-1}, t_k]\} \) of each component of \( 0 \), maximal subject to the condition that \( \tilde{\alpha}[t_{k-1}, t_k] \) intersect \( \bigcup_j D_j \) exactly in \( \tilde{\alpha}(t_{k-1}) \) and \( \tilde{\alpha}(t_k) \), for each \( k \). Furthermore, for each \( k \), \( f_j \tilde{\alpha}[t_{k-1}, t_k] \) is a canonical piece in the standard pants for some \( j \), or \( v_i \tilde{\alpha}[t_{k-1}, t_k] \) is some number of twists in the standard annulus \( A \) for some \( i \).

c) \( \tilde{\alpha} \) gives rise to the symbol, as above.
We will say an immersion \( \bar{\alpha} \) is in good position (with respect to the basis \( A \)) if there is a partition of the components of \( 0 \) so that conditions b) and c) above are satisfied. Thus, to each (parametrized) immersion in good position, there corresponds a unique symbol. However, it is not true that there is a unique homotopy class rel boundary (of the immersion) of good immersions corresponding to a given symbol.

One can easily give necessary and sufficient conditions for a symbol to arise as above from an immersion, provided that we do not require that the immersion be homotopic to an embedding. Necessary and sufficient conditions for a symbol to be either immersed admissible or embedded admissible are not known. This appears to be a very hard problem, which we will happily be able to avoid.

Note that an embedded admissible symbol is immersed admissible. Moreover, note that if \( \alpha \in \mathcal{P}'(F) \), then one can compute the parameter values \( \{l_{**}^j, t_i^j\} \) corresponding to \( \alpha \) (with respect to the basis \( A \)) from the \( A \)-symbol corresponding to \( \alpha \). Indeed, if \( c \) is a component of a good representative of \( \alpha \), then the parameter values \( l_{**}^j \) and \( t_i^j \) corresponding to the isotopy class of \( c \) are the exponent sums of the letters \( s_{**}^j \) and \( s_{*}^j \) in the symbol corresponding to \( c \). The parameter values of a disconnected \( \alpha \) are the sums of the parameter values of its components. (See Remark 2.4.) We call the various exponent sums on the letters of an arbitrary symbol the coordinates of the symbol. We will denote these exponent sums by \( l_{**}^j \) and \( t_i^j \). This abuse of notation will not cause any confusion.

Suppose that \( s s' \) is a pair of adjacent letters in the symbol \( \bar{s} \) corresponding to the immersion \( \bar{\alpha} \). Suppose that \( s \) arises from \([t_{k-1}, t_k]\), and
s' arises from \([t_k', t_{k+1}']\). We say that the symbol \(s\) is alternating if one of the following conditions holds for every pair \(s, s'\) of adjacent letters.

a) \(\overline{a}(t_{k-1}, t_k)\) and \(\overline{a}(t_k, t_{k+1})\) lie on different sides of some component of \(\bigcup_i \hat{A}_i\).

b) \(\overline{a}(t_{k-1}, t_k)\) and \(\overline{a}(t_k, t_{k+1})\) are each twists of the same direction in some annulus \(A_i\).

In particular, an embedded admissible symbol is always alternating. An immersed admissible symbol may fail to be alternating; for instance, this can happen when \(D_j = D_{j'}\), where \(j\) and \(j'\) are superscripts of consecutive letters arising from canonical pieces.

We are mostly interested in alternating, constant parity symbols because an alternating, constant parity, immersed admissible symbol can often be shown to be embedded admissible. More precisely, we will prove the following proposition.

Proposition 5.1: Suppose that \(\overline{a}\) is a good proper immersion and the symbol \(\overline{s}\) of \(\overline{a}\) is alternating, constant parity and immersed admissible. Suppose, moreover, that the coordinates of \(\overline{a}\) satisfy restrictions a)-f) of Corollary 2.1. Under these conditions, \(\overline{a}\) is homotopic rel \(\partial F\) to an embedding that has the same symbol \(\overline{s}\).

(Restrictions a)-f) of Corollary 2.1 require simply that in each embedded pair of pants \(D_j\), the canonical pieces that occur may be disjointly embedded simultaneously.)

Before we prove this proposition, we introduce some machinery, called train tracks, due to Thurston [17]. We do not use train track theory in any essential way; train tracks are simply a technical convenience in the proof of Proposition 5.1.

A properly embedded branched one-submanifold \(T\) in a compact oriented
surface is called a **train track with stops** provided $F \setminus T$ contains no null-gons, mono-gons, bi-gons or smooth annuli. (See Section 4.) In the literature, it is customary to require a **train track** to be a **closed** branched one-submanifold embedded in $F$. Our definition is more general for utility.

We construct seven train tracks with stops on the standard pair of pants using the following combinations of canonical pieces:

i) $(1_{11}, 1_{12}, 1_{13})$

ii) $(1_{22}, 1_{12}, 1_{23})$

iii) $(1_{33}, 1_{13}, 1_{23})$

iv) $(1_{12}, 1_{13}, 1_{23})$

v) $(1_{11}, 1_{12}, 1_{13})$

vi) $(1_{22}, 1_{12}, 1_{23})$

vii) $(1_{33}, 1_{13}, 1_{23})$. (Recall the alternative choices of canonical pieces indicated in Figure 2.11.) These train tracks with stops are pictured in Figure 5.1; we indicate two train tracks with stops on the standard annulus in Figure 5.2.

Let $M_1$ be the number of embedded pants $D_j$ so that no two boundary components of $D_j$ are parallel in $F$, and let $M_2 = M - M_1$. We will construct $4M_1 + 2(N + M_2)$ train tracks with stops in $F$, called the standard train tracks with stops (with respect to the basis $A$).

**Construction 5.1:** A branched one-submanifold $T$ in the surface $F$ is said to be a **standard train track with stops** with respect to the basis $A$ if the following conditions are satisfied.

a) $f_j^{-1} T$ is one of the tracks i)-vii) in the standard pair of pants corresponding to the choice of canonical pieces in the pants $D_j$, for $j=1,\ldots,M$.

b) $u_i^{-1} T$ is one of the tracks on the standard annulus illustrated in Figure 5.2, for $i=1,\ldots,N$.

c) If $D_j$ is a pair of pants so that $f_j^{-1} 1_{32}$ is parallel to $f_j^{-1} 1_{33}$ in $F$, then $f_j^{-1} T$ is one of the tracks i), iv), or v).
Figure 5.1

Figure 5.2
d) If $D_j$ is a pair of pants so that $f_j^{-1} \partial_1$ is parallel to $f_j^{-1} \partial_3$ in $F$, then $f_j^{-1} T$ is one of the tracks ii), iv) or vi).

e) If $D_j$ is a pair of pants so that $f_j^{-1} \partial_1$ is isotopic to $f_j^{-1} \partial_2$ in $F$, then $f_j^{-1} T$ is one of the tracks iii), iv) or vii).

(It is easy to check that any branched one-submanifold so constructed is actually a train track with stops. The restrictions c)-e) are explained by restrictions g)-i) of Corollary 2.1.)

Proof of Proposition 5.1: Let $\alpha$ be the particular immersion giving rise to an immersed admissible, alternating, constant parity symbol $\bar{s}$. Since the coordinates of $\bar{s}$ satisfy restrictions a)-f) of Corollary 2.1 by hypothesis, we may assume that $\alpha$ lies in a regular neighborhood $N(T)$ of one of the standard train tracks with stops, say $T$. Moreover, since $\bar{s}$ is constant parity, we may choose $T$ so that $\alpha \cap A_i$ is (smoothly) homotopic into $T \cap A_i$, for each $i=1, \ldots, N$. Since $\alpha$ consists of the pre-images under $f_j$ and $u_i$ of canonical pieces in the standard pants and twists in the standard annulus, and since $\alpha$ has an alternating symbol, there can be no mono-gons complementary to $\alpha$. Thus, by Corollary 4.1, either $\alpha$ is already embedded which proves the proposition, or there are complementary bi-gons. Let $B$ be a complementary bi-gon. Since $\alpha \subset N(T)$, $\alpha$ is (smoothly) homotopic into $T$, and $F \setminus T$ contains no bi-gons, it follows that $B \subset N(T)$. By induction on the number of times $B$ intersects $\cup \partial A_i$, one easily homotopes $\alpha$ to get rid of the bi-gon $B$, yielding an immersion homotopic to $\bar{\alpha}$, with fewer double points than $\alpha$, and with the same symbol as $\bar{\alpha}$. This proves the proposition. 

Now that we have developed some of the machinery of symbols, we give a more detailed description of the computation of the two elementary
transformations than the description given in Section 3. Recalling the notation given there, let $S_1$ be the torus-minus-a-disc, and let $S_2$ be the sphere-minus-four-discs. Let $A$ be the basis on $S_1$ indicated in Figure 3.8a, and let $A'$ be the basis on $S_1$ indicated in Figure 3.8b. Let $\pi_1: \tilde{S}_1 \to S_1$ be the regular planar cover mentioned in Section 3 (and yet to be defined) with group of covering translations $\Lambda_1$.

Given $a \in \mathcal{J}'(S_1)$, we may assume without loss (as far as computing the elementary transformations is concerned) that $t_2 = 0$ for $a \in \mathcal{J}'(S_1)$, and $t_2 = t_3 = t_4 = t_5 = 0$ for $a \in \mathcal{J}'(S_2)$. (The pants curves $\{K_i\}$ of the basis $A$ are numbered as in Figure 3.8.)

We begin by considering the elementary transforms of connected multiple arcs. If $a \in \mathcal{J}'(S_1)$ has components $\{c\}$, then the elementary transform of $a$ has $A'$ parameter values given by the sums of the $A'$ parameter values of the transforms of the components of $c$. However, recall that computing the $A$ parameter values of the components $\{c\}$ (or even the number of components) from the $A$ parameter values of $a$ is an unsolved problem. (See Remark 2.3.)

If $s$ is an $A$-symbol arising from some component $c$ of the multiple arc $\alpha$ on $S_1$, we define the $A$-length of $s$ to be the number of letters in the $A$-symbol $s$. The $A'$-length of $s$ is the number of letters in the $A'$-symbol corresponding to the isotopy class of $c$. (Using the semi-group notation, we omit any letters $st_0$ or $st_0^i$.)

We distinguish four types of connected symbols, and we will presently describe the computations for each case.

Type 1): $s$ arises from a closed component of $\alpha$; that is, $s$ corresponds to a connected multiple curve.

Type 2): $s$ arises from an arc component of $\alpha$, and both the $A$-length and the $A'$-length of $s$ are at least two.

Type 3): $s$ arises from an arc component of $\alpha$, and $s$ has $A$-length one.
Type 4): $s$ arises from an arc component of $a$, and $s$ has $A'$-length one. The typical types are 1) and 2), and we refer to connected symbols of Types 3) or 4) as exceptional. Similarly, we say that a disconnected symbol is non-exceptional if none of its components are exceptional.

Type 1): If $s$ is of Type 1), the transform of $c$ will be computed without using the machinery of symbols. We will relate the $A$- and $A'$-parameter values of multiple curves with no boundary-parallel components to the "slope" of a geodesic representative with respect to a certain metric.

We will let $\mathcal{J}'(S_1) \subset \mathcal{J}'(S_1)$ denote the collection of multiple curves with no boundary-parallel components. Similarly, if $S$ is a basis for multiple arcs, we will let $\mathcal{J}'_S(S_1) \subset \mathcal{J}'_S(S_1)$ denote the parameter values corresponding to such multiple curves with respect to the basis $S$.

Type 2): If $s$ is of type 2), suppose $s = s_1 ... s_n$ with $n \neq 1$, where the $s_i$ are $A$-letters. We will consider a lift $\tilde{c}$ of $c$ to $\tilde{S}_1$, and we will describe an isotopy between $\tilde{c}$ and some other arc $\tilde{c}$ embedded in $\tilde{S}_1$. $\tilde{c} = \Pi_1(c)$ is thus an immersion homotopic to the embedding $c$. The isotopy in $\tilde{S}_1$ will be so that we can read off the immersed admissible $A'$-symbol of the immersion $\tilde{c}$. We will check that this $A'$-symbol satisfies the hypotheses of Proposition 5.1, and we can compute the coordinates of this $A'$-symbol. This will complete the computation for Type 2) symbols.

We will describe the isotopy in $\tilde{S}_1$ in the language of symbols after making a definition.

To an embedded admissible symbol $s = s_1 ... s_n$, we let correspond a $A_1$-orbit of multiple arcs in $\tilde{S}_1$. We construct a representative of this orbit as follows: choose some good representative $c$ of the multiple arc with symbol $s$, and take some lift $\tilde{c}$ of $c$ to $\tilde{S}_1$. We may conveniently denote such a lift by $\tilde{s}_1 ... \tilde{s}_n$. We call $\tilde{s}_1 ... \tilde{s}_n$ a lift of $s_1 ... s_n$.
Lifts of symbols are convenient because there is a partition of the interval parametrizing $\tilde{c}$ by $\{[t_{k-1}, t_k]: k=1, \ldots, n\}$, so that $f_j \cap_i \tilde{c}[t_{k-1}, t_k]$ is a canonical piece in the standard pants, for some $j=1, \ldots, M$, or $u_i \cap_i \tilde{c}[t_{k-1}, t_k]$ is a sequence of twists in the standard annulus $A$, for some $i'=1, \ldots, N$. One can easily formalize this construction into the setting of semi-groups, but this geometric description is better.

We will use the correspondence of the previous paragraph in a more general setting. We will take the lift of any symbol arising from an immersed one-manifold in good position in $S_i$. $O$ may be improperly embedded in $S_i$ or even improperly immersed.

Conversely, given an arc $\tilde{c}$ (properly or improperly) embedded in $\tilde{S}_i$ with a partition as above, there corresponds an obvious symbol $s$. There is, however, no guarantee that this symbol $s$ is embedded or immersed admissible in general.

Precisely, then, for symbols of Type 2), we will describe a map from an $A$-symbol $s = s_1 \ldots s_n$ to an $A'$-symbol $\tilde{s} = \tilde{s}_1 \ldots \tilde{s}_m$ that describes an isotopy of $\tilde{s}_1 \ldots \tilde{s}_n$ to $\tilde{s}_1 \ldots \tilde{s}_m$. We will call such a map on symbols a combinatorial homotopy. Suppose for simplicity that $n > 3$. The combinatorial homotopy for type 2) symbols will be described in two stages: we first describe a combinatorial homotopy of $s_2 \ldots s_{n-1}$ to some $A'$-symbol. We then consider how we must modify this map on symbols to describe a combinatorial homotopy of all of $s_1 \ldots s_n$. This second stage, where we compute the effects of considering also the letters $s_1$ and $s_n$, is called the computation of the boundary effects.

Needless to say, for small $n$, stage 1 is not very interesting, and the transformation is governed by the boundary effects. In fact, we
treat the case of \( n \leq 4 \) separately in Appendix B. We will derive the formulas for the elementary transforms of type 2) symbols of \( A \)-length at least five in Sections 6 and 7, and then we will check by hand in Appendix B that these formulas also describe the elementary transforms of non-exceptional symbols of \( A \)-length less than five. This avoids considering several special cases in the arguments of the next two sections. I remark that several of the faces of the piecewise-integral structure of positive codimension occur when the symbols have small length, and this fact accounts for the special cases.

I should also remark that the arguments for type 2) components apply to the Type 1) components as well except for some small technical details; in fact, stage one completely describes the combinatorial homotopy for symbols of Type 1). The technical distinction between non-exceptional arcs and curves is simple: the symbols of arcs are well-defined once the arc is oriented; the symbols of curves do not enjoy this property. By the time we have given the argument that legitimizes the computations for arcs, it will be clear how to overcome this technical difficulty for multiple curves. Thus, one could give a unified treatment of Type 1) and Type 2) components. We treat these cases separately to avoid the technical difficulties and to indicate the connections between multiple curves with no boundary-parallel components and a certain Euclidean metric.

**Type 3):** If \( s \) is exceptional of type 3), then it is easy to compute the \( A' \)-parameters of the elementary transform of the component \( c \) by hand. This is tractable because of the short \( A \)-length of \( s \).

**Type 4):** We require some algorithmic procedure for deciding if
s has A'-length one. More generally, given the A-parameter value of the (potentially) disconnected $\alpha \in \mathcal{G}'(S_1)$, we will need a way to compute the number of components of $\alpha$ that have A'-length one symbols. This is again tractable because if a component $c$ of $\alpha$ has a symbol $s$ with A'-length one, then $s$ has small A-length.

Now, given the A-parameter values of some $\alpha \in \mathcal{G}'(S_1)$ with no boundary-parallel components, the computation of the corresponding A'-parameter values proceeds as follows.

**Step 1:** Compute the number of components of $\alpha$ with symbols of type 4). This immediately gives the A'-parameter values corresponding to the A'-length one A'-symbols; let $\beta$ denote the collection of components of $\alpha$ with type 4) symbols.

**Step 2:** Compute the parameter values in the basis $A$ of the multiple arc that is $\alpha$ less the components of $\alpha$ with symbols of Types 3) and 4); denote the corresponding multiple arc by $\hat{\alpha}$.

**Step 3:** Compute the parameter values in the basis $A'$ of the multiple arc $\hat{\alpha}$. (Step 3 has two stages as indicated above.)

**Step 4:** Compute the parameter values in the basis $A'$ of the components of $\alpha$ with Type 3) symbols. Denote the corresponding multiple arc by $\gamma$.

**Step 5:** The A'-parameter values of $\alpha$ are the sums (see Remark 2.4) of the A'-parameter values corresponding to $\hat{\alpha}$, $\beta$, and $\gamma$.

In Section 6 and 7, we will compute the first and second elementary transformations, respectively. In each section, we begin by defining the cover $\Pi_1: \tilde{S}_1 + S_1$. We then sketch the computation of the elementary transformations on multiple curves with no boundary-parallel components. (A sketch will suffice, because the computation for multiple curves is
a special case of the computation for Type 2) components, as mentioned above.) Next, we proceed through Steps 1-5 outlined above, and note that these computations agree with the earlier computations for multiple curves. The computations are reasonably intricate, and we will abbreviate the discourse in Sections 6 and 7 by referring to the outline of the computation given here.

We close this section by introducing some notation that will be useful in Sections 6 and 7. If $\alpha$ is a multiple arc in $S_i$ and $\mathcal{B}$ is a basis for $\mathcal{J}'(S_i)$, we will denote the tuple of parameter values corresponding to $\alpha$ with respect to the basis $\mathcal{B}$ by $(\alpha)_\mathcal{B} \in \mathcal{J}'(S_i)$. Thus, for each multiple arc $\alpha$ in the surface $S_i$, we will compute $(\alpha)_A$ from $(\alpha)_A$. 
Let $S_1$ be the torus-minus-a-disc. We begin this section by defining a regular planar cover $\pi_1: S_1 \rightarrow S_1$. Let $\Lambda_1$ be the group generated by the integral translations of $\mathbb{R}^2$, a subgroup of the group of isometries of $\mathbb{R}^2$ with its usual metric $\rho$. The quotient of $\mathbb{R}^2 \setminus \mathbb{Z}^2$ by $\Lambda_1$ is a punctured torus, and the cover of the punctured torus by $\mathbb{R}^2 \setminus \mathbb{Z}^2$ with group of translations $\Lambda_1$ is the usual cover of the torus by $\mathbb{R}^2$ with a point deleted from each fundamental domain in $\mathbb{R}^2$. Let $N$ be a small, $\Lambda_1$-equivariant, square-shaped neighborhood of $\mathbb{Z}^2$ in $\mathbb{R}^2$, as indicated in Figure 6.1. The action of $\Lambda_1$ on $\mathbb{R}^2 \setminus N$ gives a cover $\pi_1: \tilde{S}_1 \rightarrow S_1$, and the push-forward of $\rho$ to $S_1$ by $\pi_1$ gives a Euclidean structure on $S_1$ with piecewise geodesic (in fact square) boundary. To be explicit, we choose the cover so that vertical lines in $\tilde{S}_1$ cover longitudes, and horizontal lines in $\tilde{S}_1$ cover meridians in $S_1$. Much of the computation of this section will take place in the total space $\tilde{S}_1$.

![Figure 6.1](image)

Let $A$ and $A'$ be the bases for $\mathcal{P}'(S_1)$ indicated in Figure 6.2, making the choice of canonical pieces as in Construction 2.1. We will adopt
the notation of Section 2 to describe the basis $\mathcal{A}$, but we will delete the sub- and superscript 1 whenever possible since there is only one embedded pair of pants $D_j$; parameter values for multiple arcs with respect to the basis $\mathcal{A}$ are denoted by $\ell_{**}$ and $t_i$, $i=1,2$, the homeomorphism from the embedded pants $D$ to the standard pants is denoted by $f$, and so on. For convenience, we will denote the corresponding quantities and objects with respect to the basis $\mathcal{A}'$ by $\ell'_{**}$, $t'_i$, $i=1,2$, $D'$, $f'$, and so on.

![Diagram of the basis $\mathcal{A}$ and $\mathcal{A}'$](image)

**Figure 6.2**

Some remarks are in order concerning the parametrizations with respect to the bases $\mathcal{A}$ and $\mathcal{A}'$. As in restrictions g)-i) of Corollary 2.1, the two cases of simultaneously embedded canonical pieces are $\{1_{11},1_{12},1_{13}\}$ and $\{1_{12},1_{13},1_{23}\}$. Any (smooth) essential one-manifold properly embedded in $S^1$ whose corresponding multiple arc has coordinate $t_2 = 0$ is (smoothly) homotopic into one of the train tracks with stops indicated in Figure 6.3a. (See Section 5.) We give the four tracks corresponding to multiple arcs with $t'_2 = 0$ in Figure 6.3b.

Note that a connected, non-exceptional, immersed admissible $A$-symbol $\overline{s} = \overline{s}_1 \ldots \overline{s}_n$ which is not a closed component is alternating only if one of $\{\overline{s}_1,\overline{s}_n\}$ is an $s\ell_{12}$, and the other of $\{\overline{s}_1,\overline{s}_n\}$ is an $s\ell_{13}$. Thus, the coordinate value $\ell_{12}$ of such $A$-symbols is the same as the coordinate value $\ell_{13}$, and similarly for the basis $\mathcal{A}'$. 
To be quite explicit, we give in Figure 6.4a a table of the pre-images of the canonical pieces for the basis A under the homeomorphism f. In Figure 6.4a, we also give lifts (see Section 5) of the various A-letters to $\tilde{S}_1$. In Figure 6.4b, we give all the same data for the basis $A'$. 

We commence the computation of the first elementary transformation by considering first the action of this transformation on $\mathcal{G}'(S_1)$. (See Section 5.) This is a transformation between $\mathcal{G}'(S_1)$ and $\mathcal{G}'_A(S_1)$.

Lemma 1: If $\alpha \in \mathcal{G}'(S_1)$ consists of $n$ components, then $\alpha$ is $n$ parallel copies of a (connected) simple closed curve.
The basis $A$. The basis $A'$. Figure 6.4
Proof: Suppose first that \( n = 2 \), and let \( \alpha \) have components \( \alpha_1 \) and \( \alpha_2 \).

Cut \( S_1 \) along \( \alpha_1 \) to get some surface \( V \). We claim that \( V \) is connected.

For, suppose not, and let \( V_1 \) and \( V_2 \) be the components. Letting \( \chi \) denote the Euler characteristic, the following equation holds.

\[-1 = \chi(S_1) = \chi(V_1) + \chi(V_2).\]

Without loss of generality, the number of boundary components of \( V_1 \) is two, and the number of boundary components of \( V_2 \) is one. Thus \( \chi(V_1) = 2g_1 - 1 \), and \( \chi(V_2) = 2g_2 \), where \( g_1 \) is the genus of the surface \( V_1 \), \( i=1,2 \). It follows that \( g_1 + g_2 = 0 \), so \( V_2 \) is a disc, which contradicts that \( \alpha_1 \) is essential, proving the claim.

Thus, \( V \) is a pair of pants, and \( \alpha_2 \) is therefore boundary-parallel in \( V \). Since \( \alpha_2 \) is not boundary-parallel in \( S_1 \), \( \alpha_2 \) is parallel to \( \alpha_1 \).

The general case is similar. \( \Box \)

Consider the parametrization of multiple curves with no boundary-parallel components with respect to the basis \( A \). The only non-zero parameter values of a multiple curve are \( \ell_{23} \) and \( t_1 \). Using \( p,q \) curves on the torus, it is easy to construct a good connected representative corresponding to each pair of parameter values with \( \ell_{23} \) and \( |t_1| \) relatively prime, including \( \ell_{23} = 0 \) and \( t_1 = 1 \). It follows that the collection of connected multiple curves with no boundary-parallel components is parametrized by the collection \( \mathcal{P}_A(S_1) \) of parameter values satisfying the following conditions.

- a) \( \ell_{23} \) and \( |t_1| \) are relatively prime.
- b) \( \ell_{23} = 0 \) implies that \( t_1 = 1 \).
- c) \( \ell_{12} = \ell_{13} = \ell_{11} = 0 = t_2 \).

**Proposition 6.1:** There is a parametrization of connected multiple curves in \( S_1 \) with no boundary-parallel components by \( \mathcal{Q} \cup \{\infty\} \subset S_1 \), i.e., by the rational points on the circle.
Proof: Define a map $\gamma: \mathcal{P}_A(S_1) \to \mathbb{Q} \cup \{\infty\}$ by $\gamma((a)_A) = \text{sgn}(t_1)\frac{\ell_{23}}{t_1}$. Given $q = \frac{n_2}{n_1}$ with $n_1 > 0$, $n_2 \geq 0$ and $(n_1, n_2) = 1$, $\gamma^{-1}(q)$ is given by $t_1 = \text{sgn}(q)n_1$, $\ell_{23} = n_2$; $\gamma^{-1}(\infty)$ is given by $t_1 = 1$, $\ell_{23} = 0$.

The rational parametrization in the proposition can be interpreted as the "slope" of $a$ as follows: include $a \subset S_1$ in the punctured torus. Giving the punctured torus the Euclidean structure described previously, any free homotopy class has a geodesic representation, as is easy to show using the previous proposition. The Gauss-Bonnet Theorem shows that the rational slope (in the Euclidean structure) of a geodesic representative is well-defined, and this slope is exactly the rational parametrization above.

Another description of this parametrization is as follows: let $\mu$ denote the meridian, and let $\lambda$ denote the longitude of $S_1$. Given a connected multiple curve $a$ with no boundary-parallel components, isotope $a$ to have minimal geometric intersection number with the curves $\mu$ and $\lambda$, and so that $a$ does not hit the point $\mu \cap \lambda$. Then $\gamma((a)_A)$ has absolute value $\text{card}(a \cap \mu)/\text{card}(a \cap \lambda)$. Cut $S_1$ along $\mu$ and $\lambda$ to get a collection of arcs properly embedded in a disc-minus-a-disc, which inherits an orientation from $S_1$. One can show that there are four (overlapping) cases as indicated in Figure 6.5; we define the sign of $\gamma((a)_A)$ to be positive in cases one and two and negative in cases three and four. By pursuing this line of reasoning, one can prove Proposition 6.1 without resorting to Theorem 2.1.

![Figure 6.5](image-url)
Proposition 6.2: i) The first elementary transformation from the basis $\mathcal{A}$ to the basis $\mathcal{A}'$ on multiple curves with no boundary-parallel components is given by the following formulas.

\[ \ell^1_{23} = |t^1_1| \]
\[ t^1_1 = -\text{sgn}(t^1_1)\ell^1_{23} \]

In these formulas, $\text{sgn}(0) = -1$ by definition.

ii) The first elementary transformation from the basis $\mathcal{A}'$ to the basis $\mathcal{A}$ on multiple curves with no boundary-parallel components is given by the following formulas.

\[ \ell^1_{23} = |t'^1_1| \]
\[ t^1_1 = -\text{sgn}(t'^1_1)\ell^1_{23} \]

In these formulas, $\text{sgn}(0) = -1$ by definition.

Proof (sketch): First consider the case of a connected $(\alpha)_A \in \mathcal{P}'_A(S_1)$. By symmetry, there is a map $\gamma'_A: \mathcal{P}'_A(S_1) \to \mathcal{P}(\{\infty\})$ given by $\gamma'_A((\alpha)_A) = \text{sgn}(t'_1)\ell^1_{23}/|t'_1|$. We claim that the two rational parametrizations are negative reciprocals of one another. To prove this assertion, one first proves the assertions of the previous paragraph. With this description of the parametrization, it is clear that one passes from one rational parametrization to another by interchanging the curves $\mu$ and $\lambda$. This amounts to turning one's head by $90^0$ as indicated in Figure 6.6. Figure 6.6 also shows that turning one's head by $90^0$ corresponds to taking negative reciprocals of rational points on the circle. A computation proves the proposition for connected multiple curves, and the general case follows from Lemma 6.1. The convention that $\text{sgn}(0) = -1$ is the choice consistent with the convention that $m_1 = 0$ implies $t^1_1 > 0$, where $m_1$ is the Dehn-Thurston intersection number.
Having computed the first elementary transformation on multiple curves with no boundary-parallel components, we return to the general setting of \((a)_A \in \mathcal{J}_A'(S_1)\). For most of this section (until Proposition 6.3), we tacitly assume that the multiple arc \(a\) has no closed components. Without loss, we suppose that \(a\) has \(t_2 = 0\), and we orient the components of \(a\) arbitrarily. We proceed through Steps 1-5 of the computation as described at the end of Section 5. The reader should refer there to see the various steps in a wider context.

**Step 1** is to compute the number of components of \(a\) parallel to \(f^{-1}_{12}\) (plus two arcs in the annulus \(A_2\) running from window to window with no twisting). As shown in Figure 6.4, such an arc has expression \(l_{12} + l_{13}\) in the basis \(A\). We compute the number of components of \(a\) with coordinates \(l_{12} + l_{13}\) as follows: imagine cutting along the boundary of a regular neighborhood \(A_1\) of the pants curve \(K_1\). \(a\) twists \(t_1\) times in \(A_1\) and enters and exits \(3A_1\) through two windows. These windows are indicated in Figure 6.7, where the label \(w_{12}\) indicates, for instance, the region of the window through which \(f^{-1}_{12}\) may pass. Thus, the number of components of \(a\) with parameter value \(l_{12} + l_{13}\) is given by 

\[
((l_{12} - |t_1|) \Delta l_{13}) \lor 0,
\]

where \(\Delta\) is the infimum, and \(\lor\) is the supremum. Note that this expression is equal to \((l_{12} - |t_1|) \lor 0\) since the parameter values \(l_{12}\) and \(l_{13}\) of \(a\) are equal.
Step 2 is to compute the $\hat{A}$-parameter values of $\hat{a}$, the non-exceptional part of $a$. $\hat{a}$ has parameter values given by the following formulas.

\[
\hat{\ell}_{12} = \ell_{12} - (\ell_{12} - |t_1|) \vee 0 \\
\hat{\ell}_{13} = \ell_{13} - (\ell_{12} - |t_1|) \vee 0 \\
\hat{\ell}_{23} = \ell_{23} \\
\hat{\ell}_{11} = 0 \\
\hat{t}_1 = t_1 \\
\hat{t}_2 = t_2
\]

Step 3 is to compute the $A'$ parameter values of $a$ and includes the typical case. For convenience of notation, we assume that $a$ has no exceptional components, whence $(a)_A = (\hat{a})_A \in \mathcal{P}_A(S_1)$. We assume that $a$ is connected and that there is a unique embedded admissible symbol in the basis $A$, denoted $s = s_1 \ldots s_n$, corresponding to $a$, where the $s_i$ are $A$-letters.

We assume without loss, using the semi-group notation, that each
letter \( s_t^n \) appearing in \( s \) has exponent \( n \) equal to either \(+1\) or \(-1\). We assume (temporarily) that the \( A \)-length of \( s \) is at least three, and we consider the symbol \( s_2 \ldots s_{n-1} \). Note that \( s_i \in \{s_{23}t_{1}^{\pm 1}\} \), for all \( i=2,\ldots,n-1 \).

Define a map from \(<s_{23}t_{1}^{\pm 1}>\), the free semi-group on the three \( A \)-letters, to the free semi-group \(<s_{23}t_{1}^{\prime \pm 1}>\) on the \( A' \)-letters by extending the map defined below on letters.

\[
\begin{align*}
s_{23} & \rightarrow s_{1}^{-}\text{sgn}(t_{1}) \\
t_{1}^{\pm 1} & \rightarrow s_{23}^{\prime}
\end{align*}
\]

This map is realized by a homotopy of the lift \( \tilde{s_2} \ldots \tilde{s}_{n-1} \) to some arc, which we will denote \( \delta \), improperly embedded in \( \tilde{S}_1 \). The homotopy translates by \((-x,+x)\) and straightens into the lifts \( \tilde{s_{23}^{\prime}} \) and \( \tilde{t}_{1}^{\pm 1} \) in \( \tilde{S}_1 \). Thus, the homotopy is not rel endpoints.

A remark is in order concerning the sign \(-\text{sgn}(t_{1})\) of the twist that is the image of \( s_{23} \). It is obvious from the definition of the homotopy that an \( s_{23} \) in \( s \) appears as \( s_{1}^{\pm 1} \) in the symbol of \( \delta \). Lifts to \( \tilde{S}_1 \) of neighborhoods of concatenation points of \( f^{-1}l_{23} \) and twists in the annulus \( A_1 \) are shown in Figure 6.8; Figure 6.8a depicts \( \tilde{s_{23}^{\prime}} \tilde{t}_{1}^{\pm 1} \), and Figure 6.8b depicts \( \tilde{s_{23}^{\prime}} \tilde{t}_{1}^{-1} \). The solid lines in Figure 6.8 denote the lifts, and the broken lines denote the arc \( \delta \). The figure shows that when \( t_{1} \) is positive, an \( s_{23} \) in \( s \) appears as \( s_{1}^{-1} \) in the symbol of \( \delta \), and similarly when the sign of \( t_{1} \) is negative. Thus, the sign \(-\text{sgn}(t_{1})\) occurs. Note that the argument above is independent of the choice of orientation of the components of \( \alpha \). We make the convention that \( \text{sgn}(0)=-1 \); this is again the choice consistent with the convention that \( m_{1}=0 \) implies \( t_{1}>0 \). (Note, however, that \( m_{1}=0 \) cannot occur for a multiple arc with no closed components.)
To extend this map on symbols to a combinatorial homotopy from embedded admissible A-symbols to immersed admissible A'-symbols, we require the notion of a pair-of-letter expression. If $s_1$ and $s_2$ are A-letters, and if $s$ is the A-symbol corresponding to the multiple arc $\alpha$, then $(s_1, s_2)$ evaluated on $s$ is defined to be the number of times the symbol $s_1 s_2$ or $s_2 s_1$ occurs as a subsymbol of $s$. This does not depend on the orientation of the components of $\alpha$, and, for symbols on $S_4$, $(s_1, s_2) = (s_2, s_1)$. (In Section 7, where we will distinguish between the orientations on a given canonical piece, the corresponding pair-of-letter identity will not be valid.)

We describe the boundary effects (see Section 5), and thus extend the map above to a combinatorial homotopy from an embedded admissible non-exceptional A-symbol $s$ (which corresponds to the multiple arc $\alpha$) to an immersed admissible A'-symbol $\overline{s}$ (which corresponds to the good proper immersion $\overline{\alpha}$) as follows: regard the combinatorial homotopy from $\overline{s_2} \ldots \overline{s_{n-1}}$ to $\delta$ as a first approximation to the first elementary transformation from $\alpha$ to $\overline{\alpha}$. If $(s_1, s_2) \neq 0$ on $s$, where $s_1$ is one of the letters $s_{12}$ or $s_{13}$, we
modify the symbol of $\delta$ according to some rule that corresponds to an isotopy of $\tilde{s}_1 \tilde{s}_2 \ldots \tilde{s}_{n-1}$ in $\tilde{S}_1$. We adjust the symbol of $\delta$ accordingly; we will write $(s_1', s_2') \equiv \sum x'_i$ if this adjustment alters the coordinates of the symbol of $\delta$ by adding the linear combination $\sum x'_i$ of $A'$-parameter values $x'_i$ to the coordinates of the symbol of $\delta$.

As can be seen in Figure 6.9, the boundary effects are described by the following formulas. In Figure 6.9, the solid lines indicate the lift $\tilde{s}$ before the homotopy to $\delta$; the broken lines denote the improperly embedded arc $\delta$; the crossed lines denote the image of $\tilde{s}$ under our combinatorial homotopy.

\[\begin{align*}
\text{i)} (s_{l_{12}}', s_{t_1}^{-1} + 1) &\equiv -\ell_{23}' + t_2'^+1 + \ell_{13}' + t_1'^{-1} \\
\text{ii)} (s_{l_{12}}', s_{t_1}^{-1}) &\equiv \ell_{12}' + t_1'^{+1} \\
\text{iii)} (s_{l_{12}}', s_{l_{23}}') &\equiv \ell_{12}' + t_1'^{+1} \\
\text{iv)} (s_{l_{13}}', s_{t_1}^{+1}) &\equiv \ell_{12}' \\
\text{v)} (s_{l_{13}}', s_{t_1}^{-1}) &\equiv -\ell_{23}' + \ell_{13}' \\
\text{vi)} (s_{l_{13}}', s_{l_{23}}') &\equiv \ell_{12}'
\end{align*}\]
Lemma 6.2: If $\alpha$ is a multiple arc with non-exceptional symbol, then $\alpha$ is homotopic rel $3S_1$ to a good immersion $\overline{\alpha}$, where the $A'$-symbol of $\overline{\alpha}$ has $A'$-coordinates given by the following formulas.

$$
\ell'_{23} = |t_1| - (s_{l_{12}}^{-1}, s_{t_1}) - (s_{l_{13}}^{-1}, s_{t_1})
$$
$$
t'_1 = -\text{sgn}(t_1)\ell_{23} - (s_{l_{12}}^{-1}, s_{t_1}) + (s_{l_{12}}^{-1}, s_{t_1}) + (s_{l_{12}}^{-1}, s_{l_{23}}^{-1})
$$
$$
t'_2 = t_2 + (s_{l_{12}}^{-1}, s_{t_1})
$$
$$
\ell'_{13} = (s_{l_{12}}^{-1}, s_{t_1}) + (s_{l_{13}}^{-1}, s_{t_1})
$$
$$
\ell'_{12} = (s_{l_{12}}^{-1}, s_{t_1}) + (s_{l_{12}}^{-1}, s_{l_{23}}^{-1}) + (s_{l_{13}}^{-1}, s_{l_{12}}^{-1}) + (s_{l_{13}}^{-1}, s_{l_{23}}^{-1})
$$
$$
\ell'_{11} = 0
$$

Proof: Suppose first that $\alpha$ is connected. The computations above prove the lemma in case the $A$-length of the symbol of $\alpha$ is at least four since the boundary effects influence only the letters adjacent to the boundary. In Appendix B, we check by hand that the formulas above are valid for $\alpha$ not exceptional of length less than five.

Suppose finally that $\alpha \in \mathcal{P}'(S_1)$ is disconnected. It is immediate that the formulas of Lemma 6.2 also apply, provided only that the symbol of $\alpha$ is non-exceptional. This proves the lemma.

Lemma 6.3: The symbol of $\overline{\alpha}$ given by Lemma 6.2 is alternating and constant parity.

Proof: We first show that the symbol $\overline{s}$ of $\overline{\alpha}$ is alternating. Let $s = s_1 \ldots s_n$, $n \geq 4$, be the $A$-symbol of $\alpha$. It is geometrically obvious that the combinatorial homotopy on $s_2 \ldots s_{n-1}$ yields an alternating symbol $= s_2 \ldots s_{n-1}$. Moreover, the boundary effects are seen only in the letters adjacent to the boundary, and a glance at Figure 6.9i)-vi) shows that the effect of a single $s_{l_{12}}$ or $s_{l_{13}}$ letter does not destroy the property of being alternating. Thus, to prove that $\overline{s}$ is alternating, it remains to
show that s begins with an sl'_{12} if and only if it ends with an sl'_{13}. To this end, since s is embedded admissible and hence alternating and constant parity, the possible pairs of non-zero pair-of-letter expressions involving the letters sl'_{13} and sl'_{12} are the following: \{(sl'_{12},st^{+1}), (sl'_{13},st^{-1})\}, \{(sl'_{12},st^{+1}),(sl'_{13},sl'_{23})\}, \{(sl'_{12},st^{-1}),(sl'_{13},st^{-1})\}, \{(sl'_{12},sl'_{23}),(sl'_{13},st^{-1})\}, \{(sl'_{12},sl'_{23}),(sl'_{13},sl'_{23})\}, \{(sl'_{12},st^{-1}), (sl'_{13},sl'_{23})\}, \{(sl'_{12},sl'_{23}),(sl'_{13},st^{+1})\}.

The first four pairs yield an alternating symbol \(\bar{s}\), as the formulas for the boundary effects show. The last three cannot in fact occur, as shown in Figure 6.10; that is, since s is embedded admissible,

\[(sl'_{12},sl'_{23}) \neq 0\] implies that \[(sl'_{13},st^{+1}) = 0 = (sl'_{13},sl'_{23})\], and

\[(sl'_{13},sl'_{23}) \neq 0\] implies that \[(sl'_{12},st^{-1}) = 0 = (sl'_{12},sl'_{23})\]. Thus, \(\bar{s}\) is alternating.

To see that \(\bar{s}\) is constant parity, note that once again \(\bar{s}_2 \ldots \bar{s}_{n-1}\) is obviously constant parity, and the sign of the \(t'_1\) coordinate of \(\bar{s}_2 \ldots \bar{s}_{n-1}\) is \(-\text{sgn}(t'_1)\) by definition. Suppose first that \(\text{sgn}(t'_1) \geq 0\); thus, \((sl'_{12},st^{+1}) = 0\) since s is constant parity, and the formulas show that the boundary effects contribute only positive twists \(t^{+1}_1\) to the coordinates of \(\bar{s}\), preserving the property of constant parity. Finally, if \(\text{sgn}(t'_1) \geq 0\),
then \((s_{12},st^{-1}_1) = 0 = (s_{13},st^{-1}_1)\), and the only possible problem in
preserving the property of constant parity is if \((s_{12},s_{23}) \neq 0\). Figure
2.11 shows that this cannot occur since the arc \(a\) must then spiral
indefinitely around \(f_{123}^{-1}\); that is, \(t_1 > 0\) implies that \((s_{12},s_{23}) = 0\).

This proves the lemma provided the \(A\)-length of \(s\) is at least five.
The cases where the \(A\)-length of \(s\) is less than five are handled
separately in Appendix B. \(\Box\)

![Figure 6.11](image)

**Proposition 6.3:** Suppose that \(\alpha \in \mathcal{P}'(S_1)\) is a multiple arc with non-
exceptional components; the first elementary transform \((a)_A\) of \((a)_A\) has
\(A'\)-coordinates given by the following formulas.

\[
\begin{align*}
\ell'_{11} &= 0 \\
\ell'_{23} &= (|t_1| - r) \lor 0 \\
\ell'_{12} &= \ell'_{13} = r \\
t'_2 &= t_2 + (r \land t_1) \lor 0 \\
t'_1 &= -\text{sgn}(t_1)(\ell_{23} + r)
\end{align*}
\]

In these formulas, \(r = \ell_{12} = \ell_{13}\), and \(\text{sgn}(0) = -1\).

**Proof:** Just as in Step 1, one can compute the pair-of-letter expressions
in Lemma 6.2 from the parameter value of \((a)_A\) in \(\mathcal{P}'_A(S_1)\) as follows.
(s_1, s_2) = (t_1, t_2) \lor 0

(s_{12}, s_{23}) = (t_{12}, t_{23}) \lor 0

(s_{13}, s_{21}) = (t_{13}, t_{21}) \lor 0

Formally substituting the pair-of-letter values above into the formulas of Lemma 6.2 gives the following formulas.

\( \ell'_{11} = 0 \)

\( \ell'_{23} = |t_1| - (t_{12} \Delta t_1) \lor 0 - (t_{13} \Delta t_1) \lor 0 \)

\[ = |t_1| - (r \Delta t_1) \lor 0 - (r \Delta -t_1) \lor 0 \]

\[ = |t_1| - (r \Delta |t_1|) = (|t_1| - r) \lor 0 \]

\( \ell'_{12} = \ell'_{13} = (t_{12} \Delta t_1) \lor 0 + (t_{13} \Delta -t_1) \lor 0 = r \Delta |t_1| \)

\( t'_{23} = t_2 + (t_{12} \Delta t_1) \lor 0 = t_2 + (r \Delta t_1) \lor 0 \)

\[ t'_{1} = -\text{sgn}(t_1) \ell_{23} - (t_{12} \Delta t_1) \lor 0 + (t_{12} \Delta (-t_1 - t_{23})) \lor 0 \]

\[ + (-t_1 \Delta t_{12} \Delta (t_1 + t_{23} + t_{12})) \lor 0 \]

\[ = -\text{sgn}(t_1) \ell_{23} - (r \Delta t_1) \lor 0 + (r \Delta (-t_1 - t_{23})) \lor 0 \]

\[ + (-t_1 \Delta r \Delta (t_1 + t_{23} + r)) \lor 0 \]

It remains to do the algebra to show that the two expressions for \( \ell'_{12} = \ell'_{13}, \ell'_{23} \) and \( t'_{1} \) are equal.

We first consider the coordinate \( \ell'_{23} \).

\[ \ell'_{23} = \begin{cases} 
  t_1 - (r \Delta t_1), & t_1 \geq 0 \\
  -t_1 - (r \Delta -t_1), & t_1 \leq 0 
\end{cases} \]

\[ = \begin{cases} 
  t_1 - r, & t_1 \geq 0 \text{ and } r \leq t_1 \\
  0, & t_1 \geq 0 \text{ and } t_1 \leq r \\
  -t_1 - r, & t_1 \leq 0 \text{ and } r \leq -t_1 \\
  0, & t_1 \leq 0 \text{ and } -t_1 \leq r 
\end{cases} \]

\[ = (|t_1| - r) \lor 0 \]
Next we consider the coordinate \( \ell'_{12} = \ell'_{13} \). The argument at the end of Lemma 6.3 shows that \( t_1 > 0 \) implies that \( (s\ell_{12}, s\ell_{23}) = 0 \). Since
the components of \( \alpha \) are non-exceptional, an \( s\ell_{12} \) is adjacent to either an \( s\ell_{23} \) or \( s\ell^{\pm}_{1} \); it follows that \( t_1 > 0 \) implies that \( r \Delta |t_1| = r \Delta t_1 = r \). Similarly, \( t_1 < 0 \) implies that \( r \Delta |t_1| = r \Delta -t_1 \). Finally, \( t_1 = 0 \) cannot happen for a non-exceptional component. This justifies that \( \ell'_{12} = \ell'_{13} = r \Delta |t_1| = r \ell_{12} = \ell_{13} \), as one would expect.

Finally, note that the coordinate \( t'_1 \) for a non-exceptional \( \alpha \)-symbol corresponding to an arc with no closed components is non-zero. Consider the expression for \( t'_1 \).

\[
t'_1 = -\text{sgn}(t_1) \ell_{23} - (r \Delta t_1) \lor 0 + (r \Delta (-t_1 - \ell_{23})) \lor 0 \\
+ (-t_1 \Delta r \Delta (t_1 + \ell_{23} + r)) \lor 0 \\
= -\text{sgn}(t_1) \ell_{23}
\]

\[
= \begin{cases} 
-r, & t_1 > 0 \\
-r, & t_1 < 0 \text{ and } r + \ell_{23} \leq -t_1 \\
r, & t_1 < 0 \text{ and } \ell_{23} \leq -t_1 \leq \ell_{23} + r \\
r, & t_1 < 0 \text{ and } -t_1 \leq \ell_{23} \\
\end{cases}
\]

Thus, the proposition holds for multiple arcs with no closed components and no exceptional components. A computation shows that the formulas above agree with the previous computations for multiple curves, and the proposition follows. \( \square \)

The proof of the proposition applies also to closed curve components by ignoring boundary effects and allows a unified treatment of multiple arcs and multiple curves. We computed the action on multiple curves separately to indicate the connection with straightening in the Euclidean
metric on the punctured torus.

Finally, we consider Step 4. A glance at Figure 6.4 shows that an $f^{-1}_{11}$ (plus two arcs in $A_2$ running from window to window with no twisting) has an expression $t'_{12} + t'_{13} + t'_{11}$ in the basis $A'$.

**Theorem 6.1:** The first elementary transformation from the basis $A$ to the basis $A'$ is given by the following formulas.

$$t'_{11} = (r - |t_1|) \vee 0$$

$$r' = t'_{12} = t'_{13} = (r - t'_{11}) + t'_{11}$$

$$t'_{23} = (|t_1| - (r - t'_{11}))$$

$$t'_{2} = t'_{1} + t'_{11} + ((r - t'_{11}) \Delta t_1) \vee 0$$

$$t'_{1} = -sgn(t_1)(t'_{23} + (r - t'_{11}))$$

In these formulas, $r = t'_{12} = t'_{13}$, and $sgn(0) = -1$.

**Proof:** The proof is Step 5 and is the combination of the previous proposition, the sentence before this theorem and Step 1.

**Corollary 6.1:** The first elementary transformation from the basis $A'$ to the basis $A$ is given by the following formulas.

$$t_{11} = (r' - |t'_1|) \vee 0$$

$$r = t'_{12} = t'_{13} = (r' - t'_{11}) + t'_{11}$$

$$t_{23} = (|t'_1| - (r' - t'_{11}))$$

$$t_2 = t'_2 - (((r' - t'_{11}) \Delta t'_1) \vee 0 - t_{11})$$

$$t_1 = -sgn(t'_1)(t'_{23} + (r' - t'_{11}))$$

In these formulas, $r' = t'_{12} = t'_{13}$, and $sgn(0) = -1$.

**Proof:** It suffices to check that the transformations in the theorem and the corollary are inverses, which we leave as an algebraic exercise.

One can of course prove the corollary directly by mimicking the proof of the theorem with $(A,A')$ replacing $(A',A)$. This approach is about as much work as the algebraic exercise that proves the corollary.
We close this section with two final observations.

One easily derives the interesting identity $\ell'_{11} - \ell'_{23} = r - |t_1|$. If $t_1 \leq 0$, then one has the following identities.

$$
t'_2 = t_2 + \ell_{11} \\
t'_1 = \ell_{23} + (r - \ell'_{11})
$$

If $t_1 \geq 0$, then one has the following identities.

$$
t'_2 = t_2 + \ell_{11} + r - \ell'_{11} \\
t'_1 = -\ell_{23} - r + \ell'_{11}
$$

Introducing the parameter $r - |t_1|$, this gives a convenient description of the first elementary transformation as a piecewise-integral map.

The action of $\text{MC}(S_1)$ on $\mathcal{G}'(S_1)$ admits a faithful representation as an action of the two-by-two integral matrices of determinant one on $\mathcal{G}'(S_1) \subset \mathbb{Z}^+ \times \mathbb{Z}$. This is because $\text{MC}(S_1)$ is a certain central extension of the two-by-two integral matrices of determinant one by $\mathbb{Z}$. The action is a twisted right action, and will be described in Section 8.
 SECTION 7

In this section, we compute the second elementary transformation; we will follow closely the outline of Section 6. Let $S^2$ denote the sphere-minus-four-discs. We begin by defining a regular planar cover $\pi_2: S^2 \rightarrow S^2$.

Let $A_2$ be the group generated by rotations-by-$\pi$ about the integral points $\mathbb{Z}^2$ in $\mathbb{R}^2$. $A_2$ is a group of isometries of $\mathbb{R}^2 \setminus \mathbb{Z}^2$ with respect to the usual metric. This action describes a cover of the four-times punctured sphere by $\mathbb{R}^2 \setminus \mathbb{Z}^2$, and the push-forward of the usual metric by the covering projection gives a Euclidean structure on the four-times punctured sphere.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure7_1.png}
\caption{Figure 7.1}
\end{figure}

Let $N$ be a small, $A_2$-equivariant, diamond-shaped, open neighborhood of $\mathbb{Z}^2$ in $\mathbb{R}^2$, as indicated in Figure 7.1. The action of $A_2$ on $\mathbb{R}^2 \setminus N$ gives a cover of $S^2$ by $\mathbb{R}^2 \setminus N$, denoted $\tilde{S}^2$. Cutting $S^2$ along the arcs $a_1, \ldots, a_4$ in $S^2$ indicated in Figure 7.2 decomposes $S^2$ as two
octagons, labeled \( f \) and \( b \) in Figure 7.2. The lifts to \( \hat{S}_2 \) of these octagons give a tiling of \( \hat{S}_2 \); if we are careful in the choice of the geodesic arcs \( a_1 \), then we can guarantee that the associated tiling is regular. This regular tiling of \( \hat{S}_2 \) by octagons is indicated in Figure 7.3; it can be seen in the Park Street Subway Station in Boston as a tiling of \( \mathbb{R}^2 \) by squares and octagons.

Let \( A \) and \( A' \) be the bases on \( S_2 \) shown in Figure 7.4, making the choice of canonical pieces as in Construction 2.1. In contrast to Section 6, all four cases in Construction 2.1 of compatibly embedded canonical pieces can occur in each embedded pants \( D_j \), \( j=1,2 \). Thus, there are \( 512 = 4^2 \times 2^4 \) standard train tracks with stops (see Section 5) on \( S_2 \) for each basis \( A \) or \( A' \): four for each embedded \( D_j \), \( j=1,2 \),
We define a new basis $A''$ on $S_2$ as follows: the bases $A'$ and $A''$ differ only in that $A''$ uses the canonical pieces $l_{11}$ and $l_{33}$ (defined in Section 2) instead of the canonical pieces $1_{11}$ and $1_{33}$ used in the basis $A'$. Our goal is to compute the second elementary transformation between the bases $A$ and $A'$; the basis $A''$ is a technical convenience.

We introduce the following notation for this section only. We will denote the parameter values $l_{**}^1$ with respect to the basis $A$ by $l_{**}$, and we will denote the parameter values $l_{**}^2$ with respect to the basis $A$ by $k_{**}$. Similarly, the parameter values $l_{**}^1$, and $l_{**}^2$, with respect to the basis $A'$ will be denoted $l_{**}'$ and $k_{**}'$, respectively, and similarly for the basis $A''$. Moreover, $A$-symbols will be written as words in the letters $s_{\sigma}$ and $s_{\sigma'}$, and $s_{\sigma}$, $\sigma \leq \sigma' = 1, 2, 3$; we define the analogous notation for $A'$-symbols and $A''$-symbols.
Remark 7.1: Since the bases $A'$ and $A''$ differ only in the choice of canonical pieces, the transformation between the corresponding parametrizations is easily computed from Proposition A.1. The transformation from the basis $A'$ to the basis $A''$ is given by the following formulas.

$$
t_1'' = t_1' + \ell_{11}' + k_{11}'
$$

$$
t_3'' = t_3' + k_{33}'
$$

$$
t_4'' = t_4' + \ell_{33}'
$$

The other parameter values are unchanged (i.e., replace $'$ by $''$). The transformation from the basis $A''$ to the basis $A'$ is given by the following formulas.

$$
t_1' = t_1'' - \ell_{11}'' - k_{11}''
$$

$$
t_3' = t_3'' - k_{33}''
$$

$$
t_4' = t_4'' - \ell_{33}''
$$

The other parameter values are unchanged (i.e., replace $''$ by $'$).

We will want to distinguish between the orientations on $s_{11}^+$ and $sk_{11}$. Define $l_{11}^+$ and $l_{11}^-$ in the standard pants to be oriented as in Figure 7.5, and define the letters $s_{11}^{\pm}$ and $sk_{11}^{\pm}$ so that $f_1 \Pi_2 s_{11}^{\pm} = l_{11}^{\pm}$ and $f_2 \Pi_2 sk_{11}^{\pm} = l_{11}^{\pm}$. We will only need to worry about the orientations of these letters for the basis $A$, and we modify the notion of $A$-symbol to include the four letters $s_{11}^{\pm}$ and $sk_{11}^{\pm}$. (Of course, we omit the letters $s_{11}^-$ and $sk_{11}$.)

Figure 7.5
To be quite explicit, we give in Figures 7.6a and 7.6b the lifts to $\tilde{S}_2$ of the various letters for the bases $A$ and $A''$, respectively. The numbers in the deleted diamonds in Figure 7.6 indicate the boundary component twice covered by the bounding piecewise-geodesic curve in $\tilde{S}_2$; the curves are numbered as in Figure 7.4.

Note that a connected, constant parity, non-exceptional, immersed admissible symbol in the basis $A$ is alternating if and only if the letters arising from canonical pieces (instead of twists) alternate from $\sigma\ell_{**}$ to $sk_{**}$, and similarly for the bases $A'$ and $A''$. Moreover, a multiple curve has $m_1 = 2l_{11} = 2k_{11}$ in the basis $A$, where $m_1$ is the Dehn-Thurston intersection number with the pants curve $K_1$, and similarly for the bases $A'$ and $A''$.

We first compute the second elementary transformation between the bases $A$ and $A'$ on multiple curves with no boundary-parallel components using the Euclidean structure on $S_2$. We then perform steps 1-5 for multiple arcs without closed curve components between the bases $A$ and $A''$, and finally, after some algebraic manipulation, give the general form of the second elementary transformation between the bases $A$ and $A'$.

**Lemma 7.1**: If $\alpha \in \mathcal{J}'(S_2)$ consists of $n$ components, then $\alpha$ is $n$ parallel copies of a (connected) simple closed curve.

**Proof**: Suppose first that $n = 2$, and let $\alpha_1$ and $\alpha_2$ be the components of $\alpha$. Cut $S_2$ along $\alpha_1$ to get a surface $V$. We claim that $V$ is disconnected, for otherwise $\chi(V) = \chi(S_2)$, genus $(V) = \text{genus}(S_2)$ and the number of boundary components of $V$ is two greater than the number of boundary components of $S_2$, which is impossible.

Let $V$ have components $V_1$ and $V_2$, and note that $\chi(S_2) = -2 = \chi(V_1) + \chi(V_2)$.
Furthermore, if \( \chi(V_1) = 1 \), then \( V_1 \) is a disc, while if \( \chi(V_1) = 0 \), then \( V_1 \) is an annulus. Thus, since the components of \( \alpha \) are not null-homotopic and not boundary-parallel in \( S^2 \), \( V_1 \) and \( V_2 \) are each a pair of pants. If \( \alpha_2 \subset V_1 \), say, implies that \( \alpha_2 \) is parallel to one of the boundary components of \( V_1 \), whence \( \alpha_2 \) is parallel to \( \alpha_1 \). The general case is similar.

One can easily construct a (connected) simple closed curve corresponding to each pair of parameter values \( \ell_{11} \) and \( t_1 \), where \( \ell_{11} \) and \( |t_1| \) are relatively prime, including the case \( \ell_{11} = 0 \) and \( t_1 = 1 \). Thus, the subset of \( \mathcal{J}_A'(S^2) \) corresponding to connected multiple curves is the subset of \( \mathcal{J}_A'(S^2) \) so that the following conditions are satisfied.

a) \( \ell_{12} = \ell_{13} = k_{12} = k_{13} = 0 \),
\[
\ell_{22} = \ell_{23} = \ell_{33} = k_{22} = k_{23} = k_{33} = 0,
\]
and \( t_2 = t_3 = t_4 = t_5 = 0 \).

b) \( \ell_{11} = k_{11} \).

c) \( \ell_{11} \) and \( |t_1| \) are relatively prime.

**Proposition 7.1:** There is a parametrization of connected multiple curves in \( S^2 \) by \( \mathcal{J}_A'(S^2) \subset S^1 \), i.e., by the rational points of \( S^1 \).

**Proof:** Define a map \( \gamma: \mathcal{J}_A'(S^2) \rightarrow \mathcal{J}_A(\mathbb{Q}) \) by \( \gamma((\alpha)_A) = \text{sgn}(t_1 + \ell_{11}) \ell_{11}/|t_1 + \ell_{11}| \).

Given \( q = \pm n_2/n_1 \) with \( n_1 > 0 \), \( n_2 \geq 0 \) and \( (n_1, n_2) = 1 \), \( \gamma^{-1}(q) \) is \( t_1 = \text{sgn}(q)n_1 - n_2 \), \( \ell_{11} = n_2 \), and \( \gamma^{-1}(\infty) \) is \( t_1 = -1 \), \( \ell_{11} = 1 \).

Just as in Section 6, we can show that this parametrization is given by including \( \alpha \subset S^2 \subset S^1 \) minus four-points and taking the rational slope of a geodesic representative of the free homotopy class of \( \alpha \).

Again there is a more geometrical description of this parametrization, and one can prove the proposition without resorting to the main parametrization.
theorem: connect the four boundary components of $S_2$ by disjointly embedded simple arcs $a_i$ as indicated in Figure 7.2. Isotope a representative $c$ of a connected $a \in \mathcal{P}'(S_2)$ so that it has minimal geometrical intersection number with each $a_i$. $|\gamma(q)|$ is given by $\text{card}(c \cap a) / \text{card}(c \cap a')$. There are four cases indicated in Figure 7.7 for the intersection of this representative with the octagon $f$, which is indicated in Figure 7.2. The sign of $\gamma(q)$ is defined to be positive in cases one and two and negative in cases three and four. Checking that this indeed gives a parametrization for connected elements of $\mathcal{P}'(S_2)$ is a combinatorial exercise; checking that this is the parametrization described in Proposition 7.1 is case checking on the ration $t_1/m_1$. We illustrate the result of this case checking diagramatically in Figure 7.8.

![Figure 7.7](image1)

![Figure 7.8](image2)
Proposition 7.2: i) The second elementary transformation from the basis $A$ to the basis $A'$ on multiple curves with no boundary-parallel components is given by the following formulas.

\[ m'_1 = 2 |m_1/2 + t_1| \]
\[ t'_1 = -\text{sgn}(m_1/2 + t_1) (m_1 + t_1) \]

In these formulas, $\text{sgn}(0) = -1$.

ii) The second elementary transformation from the basis $A'$ to the basis $A$ on multiple curves with no boundary-parallel components is given by the following formulas.

\[ m_1 = 2 |m'_1/2 + t'_1| \]
\[ t_1 = -\text{sgn}(m'_1/2 + t'_1) (m'_1 + t'_1) \]

In these formulas, $\text{sgn}(0) = -1$.

Proof (sketch): First consider the case of a connected $\alpha \in \mathcal{P}'(S_2)$. By symmetry, there is a one-to-one onto map $\gamma': \mathcal{P}'(S_2) \to \mathbb{Q} \cup \{\infty\}$ given by $\gamma'((\alpha)_{A'}) = \text{sgn}(t'_1 + L'_1) / |t'_1 + L'_1|$, and the two rational parametrizations are negative reciprocals of one another. A computation completes the proof for connected multiple curves with no boundary-parallel components, and the general case follows from Lemma 7.1.

We now consider the general setting of $\alpha \in \mathcal{P}'(S_2)$, a multiple arc, and we compute the second elementary transformation between the bases $A$ and $A''$. Without loss of generality, suppose $\alpha$ has $A$-coordinates $t_2 = t_3 = t_4 = t_5 = 0$, and orient the components of $\alpha$ arbitrarily.

Step 1 of the computation is to compute the number of components of $\alpha$ isotopic to $f'^{-1}_{122}, f'^{-1}_{123}, f'^{-1}_{133}$ and $f'^{-1}_{122}, f'^{-1}_{22}, f'^{-1}_{23}, f'^{-1}_{33}$ in the embedded pants $D_1$ and $D_2$, respectively (plus arcs running from window to window with no twisting in the annuli $A_2, \ldots, A_5$). We first consider $f'^{-1}_{122}$ and $f'^{-1}_{123}$. As shown in Figure 7.6, an $f'^{-1}_{122}$ has $A''$-parameter
\[ \ell_{13} + k_{11} + \ell_{13} \] and an \( f^{-1}_{123} \) has parameter value \( \ell_{13} + k_{12} \). We compute the number of components of \( \alpha \) with coordinates \( \ell_{13} + k_{11} + \ell_{13} \) and \( \ell_{13} + k_{12} \) as follows: imagine cutting along the boundary of the regular neighborhood \( A_1 \) of \( K_1 \) in the basis \( A_1 \). \( \alpha \) enters and exits through the windows in \( \partial A_1 \). These windows are as indicated in Figure 7.9, where the label \( u_{12} \) \((w_{12})\) indicates, for instance, the region of the window through which \( f^{-1}_{12} \) \((f^{-1}_{22})\) may pass. One can use these decompositions of the windows to derive the following formulas:

\[ \ell_{22}'' = \left( (k_{11} + t_1) \triangle k_{11} \triangle (\ell_{13} - k_{11} - t_1 - k_{12}) \right) v \circ 0 \]
\[ \ell_{23}'' = \left( \ell_{13} \triangle k_{12} \triangle (\ell_{13} - k_{11} - t_1) \triangle (k_{12} + k_{11} + t_1) \right) v \circ 0 \]

The symmetries in Figure 7.10 immediately give the following formulas:

\[ k_{23}'' = \left( k_{13} \triangle \ell_{12} \triangle (k_{13} - \ell_{11} - t_1) \triangle (\ell_{12} + \ell_{11} + t_1) \right) v \circ 0 \]
\[ k_{22}'' = \left( (\ell_{11} + t_1) \triangle \ell_{11} \triangle (k_{13} - t_1 - \ell_{12} - \ell_{11}) \right) v \circ 0 \]
\[ \ell_{33}'' = \left( (-t_1 - k_{11}) \triangle \ell_{11} \triangle (k_{12} - \ell_{13} + t_1 + k_{11}) \right) v \circ 0 \]
\[ k_{33}'' = \left( (-t_1 - \ell_{11}) \triangle k_{11} \triangle (\ell_{12} - k_{13} + t_1 + \ell_{11}) \right) v \circ 0 \]
Step 2 is to compute the $\hat{A}$-parameter values of $\hat{\alpha}$, the non-exceptional part of $\alpha$. $\hat{\alpha}$ has parameter values given by the following formulas.

\[
\begin{align*}
\hat{\ell}_{13} &= \ell_{13} - \ell''_{23} - 2\ell''_{22} \\
\hat{k}_{12} &= k_{12} - \ell''_{23} - 2\ell''_{33} \\
\hat{\ell}_{12} &= \ell_{12} - k''_{23} - 2k''_{33} \\
\hat{k}_{13} &= k_{13} - k''_{23} - 2k''_{22} \\
\hat{k}_{11} &= k_{11} - k''_{33} - \ell''_{22} \\
\hat{\ell}_{11} &= \ell_{11} - \ell''_{33} - \ell''_{22} \\
\hat{t}_1 &= t_1 + \ell''_{33} + k''_{33} \\
\hat{t}_2 &= \hat{t}_3 = \hat{t}_4 = \hat{t}_5 = 0 \\
\hat{\ell}_{22} &= \hat{\ell}_{33} = \hat{k}_{22} = \hat{k}_{33} = 0 = \hat{\ell}_{23} = \hat{k}_{23}
\end{align*}
\]

Step 3 is to compute the $\hat{A''}$-parameter values of $\hat{\alpha}$ and includes the generic case. For convenience of notation, we assume without loss that $\alpha$ is connected and non-exceptional; thus, $(\alpha)_A = (\hat{\alpha})_A$. Suppose that $s = s_1 \ldots s_n$ is the corresponding embedded admissible $A$-symbol, and for now assume that the $\hat{A}$-length of $s$ is at least three. Note that $s_i \in \{s_{11}^\pm, s_{11}^{\pm \pm}, s_{11}^{\pm \pm ^1}\}$, for each $i=2,\ldots,n-1$.

Define a map from $<s_{11}^\pm, s_{11}^{\pm}, s_{11}^{\pm 1}>$, the free semi-group on the six $A$-letters, to the free semi-group $<s_{11}^{\pm}, s_{11}^{``}, s_{11}^{``^1}>$ on the four $A''$-letters by extending the following map defined on letters. For the time being, regard $\text{sgn}(0)$ as being undefined, and ignore the sign $\epsilon$ in the image of twists.

\[
\begin{align*}
st_{11}^{\pm 1} + s_{11}^{\phantom{11}} &\quad s_{11}^{``} \text{ or } s_{11}^{``} st_{11}^{\epsilon} \text{ or } s_{11}^{``} st_{11}^{\epsilon} s_{11}^{``}
\end{align*}
\]

\[
\begin{align*}
\begin{aligned}
s_{11}^{\pm} + s_{11}^{``} &\quad s_{11}^{``} + s_{11}^{``} \\
(s_{11}^{\pm}, st_{11}^{\pm 1}) &\equiv -2s_{11}^{``} & (s_{11}^{\pm}, st_{11}^{\pm 1}) &\equiv -2s_{11}^{``}
\end{aligned}
\end{align*}
\]

\[
\epsilon = \begin{cases} 
+1, & t_1 \geq 0. \\
-\text{sgn}(\ell_{11} + k_{11} + 2t_1), & \text{else}.
\end{cases}
\]
Pair-of-letter expressions and the notation for the pair-of-letter adjustments were defined in Section 6. (In Section 6, we adjusted only the coordinates of a symbol. Here we adjust the symbol itself.) The expression \((s_i, s_j)\) evaluated on the A-symbol \(s\) is defined exactly as in Section 6 provided neither of the letters \(s_i\) or \(s_j\) is one of the letters \(s_{11}^+\) or \(s_{11}^-\). The expression \((s_{11}^+, s_j)\) evaluated on the A-symbol \(s\), for instance, is defined to be the number of times \(s_{11}^+\) or \(s^+_i\) appears as a sub-symbol of \(s\). There is an analogous definition for pair-of-letter expressions involving the letter \(s_{11}^-\). Thus, \((s_{11}^+, st_{11}^-) = (st_{11}^-, s_{11}^-)\) and \((s_{11}^+, st_{11}^-) = (st_{11}^-, s_{11}^-)\) by definition.

We claim that this combinatorial map describes a homotopy rel endpoints from some lift \(s_2 \ldots s_{n-1}\) of \(s_2 \ldots s_{n-1}\). This can be seen as follows: begin by noting that an \(s_{11}^+ (s_{11}^-)\) has coordinate \(k_{11}^+ (k_{11}^-)\) in the basis \(A^+\). (This explains the technical facility gained by considering first the transformation between the bases \(A\) and \(A^+\).) The homotopy rel endpoints of the lift \(st_{11}^+\) to \(st_{11}^+, st_{11}^+\) or \(st_{11}^-\) is indicated in Figure 7.11a. The adjustments for the pair-of-letter expression \((sk_{11}^+, st_{11}^-)\) are indicated in Figure 7.11b. As usual, the solid lines denote the lifts, and the broken lines denote the image of the homotopy. The adjustments for the expression \((s_{11}^+, st_{11}^-)\) are similar to the adjustments in Figure 7.11b.

![Figure 7.11a](image1)

![Figure 7.11b](image2)
Note that the combinatorial homotopy above has the property that the only way to produce a \( st_{1}^{+1} \) letter in the \( A'' \)-symbol image is from an \( st_{1}^{+1} \) letter in the \( A \)-symbol. Moreover, the pair-of-letter adjustments never affect \( st_{1}^{+1} \) letters; however, the sign \( \epsilon \) of the \( t_{1}^{''} \) coordinate does depend on the pair-of-letter adjustments, as we shall see.

We say that a non-twist letter is "stable" if it is unaffected by the pair-of-letter adjustments. Note that for \( s \) an embedded admissible sequence of letters \( s^{\pm}_{11} \) and \( s^{\pm}_{k11} \), the image \( A'' \)-symbol is necessarily alternating since \( s \) is. Furthermore, if \( s \) is an embedded admissible sequence of letters \( st_{1}^{+1} \), then the image \( A'' \)-symbol is an alternating and constant \(+1\) parity image \( (s^{\pm}_{11} st_{1}^{+1} s^{\pm}_{k11})^{m} \) or \( (sk_{11}^{+1} st_{1}^{+1} s^{\pm}_{11})^{m} \).

**Claim 7.1:** If \( t_{1} \geq 0 \), then the combinatorial homotopy above on \( s_{2} \ldots s_{n} \) has an alternating and constant parity \( A'' \)-symbol image.

**Proof:** By the previous paragraph, consecutive sequences of letters \( st_{1}^{+1} \) and consecutive sequences of \( s^{\pm}_{11} \) and \( s^{\pm}_{k11} \) letters each have an alternating and constant \(+1\) parity image. A neighborhood of a concatenation point of \( \tilde{s}^{\pm}_{11} \) and \( \tilde{st}_{1}^{+1} \) is shown in Figure 7.12; the lift is denoted by a solid line and the image under the combinatorial homotopy by a broken line. Concatenation points of \( \tilde{s}^{\pm}_{k11} \) and \( \tilde{st}_{1}^{+1} \) are similar. Thus, in a neighborhood of a concatenation point, the homotopy preserves the alternating character, and the claim follows. Note that there are no pair-of-letter adjustments. \( \Box \)

![Figure 7.12](image-url)
Claim 7.2: If $t_1 < 0$, then the combinatorial homotopy above has an alternating $A^*$-symbol image.

Proof: Denote by $s''_1 \ldots s''_n$ the $A^*$-symbol image of $s_2 \ldots s_{n-1}$ under the homotopy, where the $s''_i$ are $A^*$-letters, and suppose not. Without loss of generality (by rotation-by-$\pi$ about the line $l$ in Figure 7.13a), there is some $s''_r = s''_{r+1} = s''_{r+2} = \ldots = s''_{r+m}$ with $s''_{r+1}, \ldots, s''_{r+m-1}$ twists.

There are two cases.

Case 1): $s''_r$ arose from some $s_k = s''_{k+1}$.
Case 2): $s''_r$ arose from some $s_k = s'_{k+1}$.

In Case 1), since $s$ is alternating, $s_{k+1} = st_{1}^{-1}$, or $s_{k+1} = s''_{k+1}$.

If $s_{k+1} = st_{1}^{-1}$, then, by Proposition A.3, the homotopy would have erased $s''_r = s''_{k+1}$ as in Figure 7.13b, which is absurd. Thus, $s_{k+1} = s''_{k+1}$. If $s_{k+2} = s''_{k+2}$, then $s_{r+1} = s''_{r+1}$ and $s_{r+1}$ is stable, which is contradictory to hypothesis. Thus, $s_{k+2} = st_{1}^{-1}$, and so we must have $s_{k+1} = s''_{k+1}$ by Proposition A.2. In Case 2), if $s_k = s''_{k+1}$, we must have $s_{k+3} = s''_{k+1}$ as indicated in Figure 7.13a, so that $s''_{r+1} = st_{1}^{-1}$. If $s_{r+4} = s''_{r+4}$, then $s_{r+2} = s''_{r+2}$ and $s''_{r+2}$ is stable, which is contradictory to hypothesis; thus, $s_{k+4} = s''_{k+4}$, $s_{k+5} = st_{1}^{-1}$, $s_{k+6} = s''_{k+6}$ and $a$ is forced to spiral around $\Pi_2 s''_{k+1} \Pi_2 s''_{k+2} \Pi_2 st_{1}^{-1}$ indefinitely, which is absurd.

Figure 7.13
In case $\kappa = \kappa$, we must have $\kappa+3 = \kappa$ as indicated in Figure 7.13b, so that $s''_{r+1} = s''_{r-1}$. If $\kappa+3 = \kappa^+$, then $\kappa-1 = \kappa^-$, and the homotopy would have erased $\kappa$, which is absurd. If $\kappa+4 = \kappa^-$, then $s''_{r+2} = \kappa''_{r+1}$ and $s''_{r+2}$ is stable, which is contrary to hypothesis; thus, $s_{k+4} = \kappa^-$, $s_{k+5} = \kappa^-$, and $\alpha$ is forced to spiral indefinitely around $\Pi_2 \kappa^-$ $\Pi_2 \kappa^+$ $\Pi_2 \kappa^-$ $\Pi_2 \kappa^-$. Thus, Case 1) cannot lead to a non-alternating image $A'$-symbol.

In Case 2), there are two sub-cases.

Sub-case a): $\kappa$ leads to $s''_{r+1} = s''_{r+1} \kappa^+$ $\kappa^-$ $\kappa^+$.

Sub-case b): $\kappa$ leads to $s''_{r+1} = s''_{r+1} \kappa^+$ $\kappa^-$ $\kappa^+$.

In Sub-case a), since $t_1 < 0$, $\kappa+1 = \kappa^+$. If $\kappa+1 = \kappa^-$, then the homotopy erases $s''_r$, which is absurd; thus, we assume that $\kappa+1 = \kappa^+$. By Proposition A.2, $\kappa+2 = \kappa^+$, so $\kappa+3 = \kappa^-$. This case is indicated in Figure 7.14a. Thus, $\kappa+4 = \kappa^+$, $\kappa+5 = \kappa^-$, and $\alpha$ must spiral indefinitely about $\Pi_2 \kappa^+ \Pi_2 \kappa^- \Pi_2 \kappa^-$, which is absurd.

Figure 7.14
In Sub-case b), since \( t_1 < 0 \), \( s_{k+1} = s_{ll}^{\pm} \). If \( s_{k+1} = s_{ll}^{\pm} \), then the

\( s_{ll}^{\pm} \) arising from \( s_k \) is stable, contradictory to hypothesis; thus, we

assume that that \( s_{k+1} = s_{ll}^{-} \). If \( s_{k+2} = s_{ll}^{-1} \), then the \( s_{ll}^{\pm} \) arising

from \( s_{k+2} \) is stable, contradictory to hypothesis; thus \( s_{k+2} = s_{ll}^{\pm} \) and

\( s_{k+3} = s_{ll}^{-1} \), so that \( s_{k+2} = s_{ll}^{\pm} \) by Proposition A.2. This configuration

is indicated in Figure 7.14b. If \( s_{k+4} = s_{ll}^{\pm} \), then the \( s_{ll}^{\pm} \) arising

from \( s_{k+4} \) would be stable, contradictory to hypothesis; thus, \( s_{k+4} = s_{ll}^{-} \),

and a must spiral indefinitely about \( s_{ll}^{-} s_{ll}^{+} s_{ll}^{-} s_{ll}^{+} \), which is

absurd. Thus, Case 2), cannot lead to a non-alternating image \( A''\)-symbol,

proving the claim.\( \Box \)

Claim 7.3: The \( A''\)-symbol image of the combinatorial homotopy above has

all its twists in the same direction.

Proof: By the previous claim, the sign of a consecutive block of twists

of \( s'' \) ... \( s'' \) is well-defined. Thus, it suffices to prove that if

\( s_{r} = s_{r}^{\pm} \) and \( s_{r+m}^{'} = s_{r+m}^{'} \), with \( s_{r}^{'} \), ..., \( s_{r+m-1}^{'} \) \( \in \{ s_{ll}^{\pm}, s_{ll}^{-} \} \), then

\( s_{r}^{'} \) and \( s_{r+m}^{'} \) have the same sign, \( m \neq 1 \). Suppose then that \( s_{r}^{''} \) arose from

\( s_k \) leading to \( s_{ll}^{''} s_{ll}^{+'} \). In this case, either \( s_{k+1} = s_{ll}^{-1} \), which

is acceptable (and \( m=3 \) with \( sgn(s_{r}^{''}) = sgn(s_{r+m}^{''}) = +1 \)), or \( s_{k+1} = s_{ll}^{\pm} \),

by Proposition A.2. There are then two cases.

Case 1): \( s_{r+m}^{''} \) arose from \( s_j \) leading to \( s_{ll}^{''} s_{ll}^{+'} s_{ll}^{''} \).

Case 2): \( s_{r+m}^{''} \) arose from \( s_j \) leading to \( s_{ll}^{''} s_{ll}^{+'} s_{ll}^{''} \).

In Case 1), \( s_{j-1} = s_{ll}^{\pm} \) by Proposition A.4, which is acceptable

(and \( sgn(s_{r}^{''}) = sgn(s_{r+m}^{''}) = -1 \)), and in Case 2), \( s_{j-1} = s_{ll}^{\pm} \) by Proposition

A.4, which is acceptable (and again \( sgn(s_{r}^{''}) = sgn(s_{r+m}^{''}) = -1 \)).

The case where \( s_{r+m}^{''} \) arises from \( s_j \) leading to \( s_{ll}^{''} s_{ll}^{+'} s_{ll}^{''} \) is

similar, proving the claim.\( \Box \)
Claim 7.4: The sign $\varepsilon''$ of the $t_1'$ coordinate of $s_1'' \ldots s_n''$ is given by the following formula

$$
\varepsilon'' = \begin{cases} 
-s\text{gn}(2t_1 + \ell_1 + k_1), & t_1 < 0 \\
+1, & t_1 \geq 0
\end{cases}
$$

This formula is valid unless $s_1'' \ldots s_n''$ is a sequence of twists, in which case $\varepsilon''$ is undefined and $s_2'' \ldots s_{n-1}$ is given by $(s\ell_1^+ s_{t_1}^{-1} s\ell_1^-)^m$ or $(sk_1^+ s_{t_1}^{-1} s\ell_1^-)^m$.

Proof: If a letter $s_{t_1}$ is not surrounded in $s$ on both sides by $s\ell_1^+$ and $s\ell_1^-$, then the corresponding $t_1''$ has a positive sign, and the first part of the claim follows from Claim 7.3. That $s_2'' \ldots s_{n-1}$ is $(s\ell_1^+ s_{t_1}^{-1} s\ell_1^-)^m$ or $(sk_1^+ s_{t_1}^{-1} s\ell_1^-)^m$ in case $\varepsilon''$ is undefined is an easy combinatorial argument. $\Box$

The previous four claims prove the following proposition.

Proposition 7.3: The combinatorial homotopy above on $s_2'' \ldots s_{n-1}$ gives an alternating and constant parity $A''$-symbol with $\varepsilon'' = -s\text{gn}(\ell_1 + k_1 + 2t_1)$ if $t_1 < 0$, $\varepsilon'' = +1$ if $t_1 \geq 0$, and $s\text{gn}(0)$ (as yet) undefined. $\Box$

(The disparity between the cases $t_1 < 0$ and $t_1 \geq 0$ is reflected in Figure 7.8. The connection between the $\varepsilon''$ just computed and the ratio $t_1/m_1$ is explained in Remark 7.1.)

We describe the boundary effects and extend the combinatorial homotopy above to a combinatorial homotopy from embedded admissible non-exceptional $A$-arcs to immersed admissible non-exceptional $A''$-arcs.

Figure 7.15 depicts the homotopies described by the following pair-of-letter adjustments. As usual, the solid lines in Figure 7.15 depict the lifted letters, and the broken lines in Figure 7.15 depict the image under the combinatorial homotopy.
a) \((s_{12}, st_{1}^{+}) = k_{13}''\)

b) \((s_{12}, st_{1}^{-}) = -t_{3}'' - k_{11}'' + k_{13}''\)

c) \((s_{12}, sk_{11}^{-}) = k_{13}''\)

d) \((s_{12}, sk_{11}^{+}) = k_{13}''\)

e) \((s_{13}, st_{1}^{+}) = \ell_{12}'' + t_{2}'' - \ell_{11}'' - t_{1}''\)

f) \((s_{13}, st_{1}^{-}) = \ell_{12}''\)

g) \((s_{13}, sk_{11}^{+}) = \ell_{12}''\)

h) \((s_{13}, sk_{11}^{-}) = -\ell_{11}'' + t_{2}'' - t_{1}'' + \ell_{12}''\)

i) \((sk_{12}, st_{1}^{+}) = \ell_{13}''\)

j) \((sk_{12}, st_{1}^{-}) = \ell_{13}'' - t_{4}'' - \ell_{11}''\)

k) \((sk_{12}, s\ell_{11}^{+}) = \ell_{13}''\)

l) \((sk_{12}, s\ell_{11}^{-}) = \ell_{13}''\)

m) \((sk_{13}, st_{1}^{-}) = -t_{1}'' + t_{5}'' - k_{11}'' + k_{12}''\)

n) \((sk_{13}, st_{1}^{+}) = k_{12}''\)

o) \((sk_{13}, s\ell_{11}^{-}) = k_{12}'' - k_{11}'' + t_{5}'' - t_{1}''\)

p) \((sk_{13}, s\ell_{11}^{+}) = k_{12}''\)

---

**Figure 7.15**
Proposition 7.4: If \( \alpha \) is not a closed component and its symbol is non-exceptional, then \( \alpha \) is homotopic rel \( \partial S_2 \) to an immersion \( \alpha'' \), where \( \alpha'' \) has an \( \text{A}'' \)-symbol with the following \( \text{A}'' \) coordinates.

\[
\begin{align*}
t''_1 &= -(s\ell_{13},st_{1}^{+1}) - (s\ell_{13},sk_{11}^-) - (sk_{13},st_{1}^{+1}) - (sk_{13},s\ell_{11}^-) \\
&\quad + \text{sgn}(l_{11}+k_{11}+2t_1) t_1 \\
t''_2 &= (s\ell_{13},st_{1}^{+1}) + (s\ell_{13},sk_{11}^-) \\
t''_3 &= -(s\ell_{12},st_{1}^{-1}) \\
t''_4 &= -(sk_{12},st_{1}^{-1}) \\
t''_5 &= (sk_{13},s\ell_{11}^-) + (sk_{13},st_{1}^{+1}) \\
\ell''_{12} &= \ell_{13} \quad k''_{12} = k_{13} \\
\ell''_{13} &= k_{12} \quad k''_{13} = \ell_{12} \\
\ell''_{23} &= \ell''_{22} = \ell''_{33} = k''_{23} = k''_{22} = k''_{33} = 0 \\
k''_{11} &= |t_1| + \ell_{11} - 2(s\ell_{11}^+,st_{1}^{-1}) - (s\ell_{12},st_{1}^{-1}) - (sk_{13},st_{1}^{+1}) - (sk_{13},s\ell_{11}^-) \\
\ell''_{11} &= |t_1| + k_{11} - 2(sk_{11}^+,st_{1}^{-1}) - (s\ell_{13},st_{1}^{+1}) - (s\ell_{13},sk_{11}^-) - (sk_{12},st_{1}^{-1})
\end{align*}
\]

In these formulas, the convention for \( \text{sgn}(0) \) is the following.

\[
\text{sgn}(0) = \begin{cases} 
+1, & \text{if a has symbol } s\ell_{12}^+ (sk_{11}^+ st_{1}^{-1} s\ell_{11}^-)^m sk_{12}^+ \\
-1, & \text{if a has symbol } s\ell_{13}^+ (sk_{11}^+ st_{1}^{-1} s\ell_{11}^-)^m sk_{13}^+
\end{cases}
\]

Moreover, the symbol of \( \alpha'' \) is alternating and constant parity.

Proof: We check by hand in Appendix B that the proposition holds when the \( \text{A} \)-symbol of \( \alpha \) has \( \text{A} \)-length four or less; we will assume here that the \( \text{A} \)-length of the symbol \( s \) of \( \alpha \) is at least five. Let \( \bar{s''} \) be the symbol of \( \bar{\alpha''} \).

Claims 7.1-7.4 above imply that the image of \( s_2 \ldots s_{n-1} \) under the map above is alternating and constant parity, and we begin by considering the boundary effects in the total space \( S_2 \). In this setting, \( (s\ell_{12},st_{1}^{+1}) \), \( (sk_{13},st_{1}^{+1}) \), \( (s\ell_{13},st_{1}^{+1}) \), and \( (sk_{12},st_{1}^{+1}) \) are all obviously alright.
Moreover, \((s_{12},sk_{11})\) and \((sk_{12},s_{11})\) are both alright by Proposition A.2 ii) and i), respectively.

In the case of \((s_{13},sk_{11})\) (and the case of \((sk_{13},s_{11})\) by symmetry), either \(s\) is of \(A\)-length three (and perhaps exceptional) or \(sk_{11}\) is stable, so that \(s''\) is alternating. To see that \(s''\) is constant parity, we must show that the \(t''_1\) coordinate of \(s''\) is negative if the pair-of-letter expression \((s_{13},sk_{11})\) is non-zero. If \(s_1 = s_{13}, s_2 = sk_{11}, \) and \(s_3 = st_{1}^{+\ast}\), then \(s\) is of \(A\)-length four as indicated in Figure 7.16a. We assume then that \(s_3 = s_{11}^{-}\). In case \(s_3 = s_{11}^{+}\), it is geometrically obvious from Figure 7.16b that \(s\) has \(t_1\) coordinate value equal to zero. In case \(s_3 = s_{11}^{+}\), either \(s\) is of \(A\)-length four, \(s_4 = st_{1}^{-}\) and \(s\) has negative twisting by Claim 7.3 as in Figure 7.16c, or \(s_4 = sk_{11}^{+}\). In this last case, either \(s\) is of length five and the proposition holds, as shown in Figure 7.16d, or \(s_5 = t_1^{-}\) and \(s''\) has negative twisting by Claim 7.3, as in Figure 7.16e.
In the case of \((s_{12}^+, s_{11}^+)\) (and the case of \((s_{12}^-, s_{11}^-)\) by symmetry), \(s''\) is alternating and constant parity if \(s_{11}^+\) is stable; thus, we suppose that \(s_1 = s_{12}^+, s_2 = s_{11}^+,\) and \(s_3 = s_{11}^-.\) Either \(s\) is of A-length four, or \(s_4 = s_{11}^-\). Thus, either \(s_5 = s_{12}^+,\) and \(s\) is of A-length five with a negative twisting number, as indicated in Figure 7.17, or \(s_5 = s_{12}^+\). If \(s_5 = s_{11}^+,\) then either \(s_6 = s_{12}^+,\) which gives a negative twisting number, as indicated in Figure 7.18, or \(s_6 = s_{11}^-\).

If \(s_5 = s_{11}^-\), then \(s_{11}^-\) is stable, and \(s''\) is alternating and constant parity.

The general case is identical to the above with a winding about
\(\pi_2 s_{11}^+ \pi_2 s_{11}^- \pi_2 s_{11}^+\) followed by \(\pi_2 s_{11}^- \pi_2 s_{12}^-\) or \(\pi_2 s_{11}^- \pi_2 s_{13}^-\). The former is alternating and constant parity since \(s_{11}^-\) is stable, and the latter cases are alternating and constant parity as indicated in Figure 7.17 and 7.18, respectively. Note that \(\text{sgn}(0) = +1\) is the appropriate convention here.
Finally, in case of \((s^\ell_{13}, sk^+_11)\) (and the case of \((sk^s_{13}, s^\ell_{11})\) by symmetry), either \(s_1 = s^\ell_{13}\), \(s_2 = sk^+_11\), and \(s_3 = s^\ell_{13}\), so that \(s\) is exceptional, or \(s_3 = st_1^{-1}\). If \(s_4 = s^\ell_{12}\), then \(s\) has A-length four as indicated in Figure 7.19. If \(s_4 = s^\ell_{11}\), then \(s_5 = st_1^{-1}\), and the \(sk^s_{11}\) arising from \(s_3\) is stable. If \(s_4 = s^\ell_{11}\) and \(s_5 = sk^s_{13}\), then \(\bar{s}\) is alternating and constant parity, as indicated in Figure 7.19. If \(s_5 = st_1^{-1}\), then \(s_6 = sk^s_{11}\), and the \(sk''_{11}\) arising from \(s_5\) is stable, and \(\bar{s}\) is alternating and constant parity. Thus, suppose that \(s_4 = s^\ell_{11}\) and \(s_5 = sk^s_{11}\); this implies that \(s_6 = st_1^{-1}\). The general case is identical to the above with a winding about \(\Pi_2^{\tilde{\text{sk}}_{11}} \Pi_2^{st_1^{-1}} \Pi_2^{s^\ell_{11}}\) followed by \(\Pi_2^{\tilde{\text{sk}}_{13}}\), as indicated in Figure 7.20; or followed by \(\Pi_2^{\tilde{\text{sk}}_{11}} \Pi_2^{st_1^{-1}} \Pi_2^{s^\ell_{12}}\) as in Figure 7.19; or followed by \(\Pi_2^{\tilde{\text{sk}}_{11}} \Pi_2^{st_1^{-1}} \Pi_2^{s^\ell_{11}}\), and the \(sk''_{11}\) arising from this last twist is stable; or followed by \(\Pi_2^{\tilde{\text{sk}}_{11}}\) and the \(sk''_{11}\) arising from the last twist is stable. Note that \(\text{sgn}(0) = -1\) is the appropriate convention here.

\end{figure}
Proposition 7.5: Suppose that \( \alpha \) is a non-exceptional multiple arc on \( S_2 \). The parameter values \( (\alpha)_A'' \) are determined from the parameter values \( (\alpha)_A' \) by the following formulas.

\[
\begin{align*}
\ell_{12}'' &= \ell_{13}'' = k_{12}'' = k_{13}'' = 0 \\
\ell_{23}'' &= \ell_{22}'' = \ell_{33}'' = k_{23}'' = k_{22}'' = k_{33}'' = 0 \\
t_2'' &= (\ell_{13} + (k_{11} + t_1)) \lor 0 + t_2 \\
t_3'' &= (\ell_{11} + t_1) \lor -\ell_{12}'' \lor 0 + t_3 \\
t_4'' &= (k_{11} + t_1) \lor -k_{12}'' \lor 0 + t_4 \\
t_5'' &= (k_{13} + (\ell_{11} + t_1)) \lor 0 + t_5 \\
t_1'' &= \text{sgn}(2t_1 + \ell_{11} + k_{11}) t_1 - (t_2'' - t_2) -(t_5'' - t_5) \\
k_{11}'' &= (t_1 - k_{13} + \ell_{11}) \lor 0 + (-t_1 - \ell_{11} - \ell_{12}) \lor 0 \\
\ell_{11}'' &= (t_1 - \ell_{13} + k_{11}) \lor 0 + (-t_1 - k_{11} - k_{12}) \lor 0 
\end{align*}
\]

In these formulas, \( \text{sgn}(0) \) is defined as follows.

\[
\text{sgn}(0) = \begin{cases} 
+1, & \text{if } \ell_{12}'' \neq 0 \\
-1, & \text{else}.
\end{cases}
\]

Proof: Just as in Step 1, one can compute the pair-of-letter expressions in Proposition 7.4 from the parameter values \( (\alpha)_A' \) as in the following formulas.

\[
\begin{align*}
(s_{l_{13}}, s_{t_{13}}^{-1}) &= (\ell_{13} \lor t_1) \lor 0 \\
(s_{k_{13}}, s_{t_{13}}^{-1}) &= (k_{13} \lor t_1) \lor 0 \\
(s_{l_{13}}, s_{k_{11}}^{-1}) &= (\ell_{13} \lor k_{11} \lor (\ell_{13} - t_1) \lor (k_{11} + t_1)) \lor 0 \\
(s_{k_{13}}, s_{l_{11}}^{-1}) &= (k_{13} \lor \ell_{11} \lor (k_{13} - t_1) \lor (\ell_{11} + t_1)) \lor 0 \\
(s_{l_{11}}^{+}, s_{t_{11}}^{-1}) &= (\ell_{11} \lor -t_1) \lor 0 \\
(s_{k_{11}}^{+}, s_{t_{11}}^{-1}) &= (k_{11} \lor -t_1) \lor 0 \\
(s_{l_{12}}^{+}, s_{t_{12}}^{-1}) &= ((-t_1 - \ell_{11}) \lor \ell_{12}) \lor 0 \\
(s_{k_{12}}^{+}, s_{t_{12}}^{-1}) &= ((-t_1 - k_{11}) \lor k_{12}) \lor 0
\end{align*}
\]
We begin by considering the case where \( \alpha \) has no closed curve components, and we plug the formulas above for the pair-of-letter expressions into the formulas of Proposition 7.4. All of the formulas of this proposition follow immediately except for the expressions for the parameters \( t_2'', t_5'', \ell_{11}'' \) and \( k_{11}'' \). We must do some algebraic manipulation for these parameter values. We will perform the computations for the parameters \( t_2'' \) and \( k_{11}'' \); the algebra for the parameters \( t_5'' \) and \( \ell_{11}'' \) is similar.

\[
t_2'' = (\ell_{13} \Delta t_1) \lor 0 + (\ell_{13} \Delta k_{11} \Delta (\ell_{13} - t_1) \Delta (k_{11} + t_1)) \lor 0
\]

\[
= \begin{cases} 
\ell_{13} \Delta t_1 + ((\ell_{13} - t_1) \Delta k_{11}) \lor 0, & t_1 \geq 0 \\
(\ell_{13} \Delta (k_{11} + t_1)) \lor 0, & t_1 \leq 0
\end{cases}
\]

\[
t_1 + \ell_{13} - t_1, \ t_1 \geq 0 \ & \ 0 \leq (\ell_{13} - t_1) \leq k_{11}
\]

\[
= \begin{cases} 
\ell_{13}, & t_1 \geq 0 \ & (\ell_{13} - t_1) \leq 0 \\
(\ell_{13} \Delta (k_{11} + t_1)) \lor 0, & t_1 \leq 0
\end{cases}
\]

\[
= (\ell_{13} \Delta (k_{11} + t_1)) \lor 0, \ \text{as desired.}
\]

\[
k_{11}'' = |t_1| + \ell_{11} - 2((\ell_{11} \Delta t_1) \lor 0) - (\ell_{11} \Delta \ell_{12} \lor 0)
\]

\[
- ((k_{13} \Delta t_1) \lor 0) - ((k_{13} \Delta \ell_{11} \Delta (k_{13} - t_1) \Delta (\ell_{11} + t_1)) \lor 0)
\]

\[
= \begin{cases} 
t_1 + \ell_{11} - (k_{13} \Delta t_1) - ((k_{13} - t_1) \Delta (k_{11} + t_1)) \lor 0, & t_1 \geq 0 \\
-t_1 + \ell_{11} - 2(\ell_{11} \Delta -t_1)
\end{cases}
\]

\[
-((-t_1 \lor \ell_{11} \lor 0) - (k_{13} \Delta (\ell_{11} + t_1)) \lor 0), & t_1 \leq 0
\]
\[
\begin{cases}
  t_1 + \ell_{11} - k_{13}, & t_1 \geq 0 \& t_1 \geq k_{13} \\
  t_1 + \ell_{11} - t_1 - k_{13} + t_1, & t_1 \geq 0 \& k_{13} - \ell_{11} \leq t_1 \leq k_{13} \\
  t_1 + \ell_{11} - t_1 - \ell_{11}, & t_1 \geq 0 \& k_{13} - \ell_{11} \\
  t_1 + \ell_{11} - k_{13}, & t_1 \leq 0, \quad -t_1 \leq \ell_{11} \& k_{13} \leq \ell_{11} + t_1 \\
  t_1 + \ell_{11} - \ell_{11} - t_1, & t_1 \leq 0, \quad -t_1 \leq \ell_{11} \& \ell_{11} + t_1 \leq k_{13} \\
  -t_1 - \ell_{11} - \ell_{12}, & t_1 \leq 0, \quad -t_1 \leq \ell_{11} \& \ell_{12} \leq -t_1 - \ell_{11} \\
  -t_1 - \ell_{11} + t_1 + \ell_{11}, & t_1 \leq 0, \quad -t_1 \leq \ell_{11} \& -t_1 - \ell_{11} \leq \ell_{12}
\end{cases}
\]

\[= (t_1 - k_{13} + \ell_{11}) \lor 0 + (\ell_{11} - \ell_{12}) \lor 0, \text{ as desired.}\]

To complete the proof of the proposition, one checks that the formulas of Proposition 7.5 agree with the earlier computations for multiple curves using Remark 7.1. We leave this as an exercise. 

Finally, we consider Step 4. We abuse notation slightly and describe the \(A''\)-coordinate values of the various exceptional arcs of \(A\)-length one using the notation for the pair-of-letter adjustments.

\[
\begin{align*}
  s'_{k22} & = 2\ell''_{13} + t''_1 + k''_{11} \\
  s'_{k33} & = 2k''_{12} + \ell''_{11} + t''_5 \\
  s'e_{22} & = 2k''_{13} + \ell''_{11} + t''_1 \\
  s'e_{33} & = 2\ell''_{12} + t''_2 + k''_{11} \\
  s'e_{23} & = \ell''_{12} + k''_{13} \\
  s'_{h23} & = \ell''_{13} + k''_{12}
\end{align*}
\]

At last, we are in a position to give the formulas that describe the second elementary transformation. Note that we have performed Steps 1-5 between the bases \(A\) and \(A''\).
Theorem 7.1: The second elementary transformation from the basis $A$ to the basis $A'$ is given by the following formulas.

\[
\begin{align*}
  k_{11}' & = k_{22} + \ell_{33} + (L - k_{13}) \vee 0 + (-L - \ell_{12}) \vee 0 \\
  k_{22}' & = (L \land \ell_{11} \land (k_{13} - \ell_{12} - L)) \lor 0 \\
  k_{33}' & = (-L \land k_{11} \land (\ell_{12} - k_{13} + L)) \lor 0 \\
  k_{23}' & = (k_{13} \land \ell_{12} \land (k_{13} - L) \land (\ell_{12} + L)) \lor 0 \\
  k_{12}' & = -2k_{22}' - k_{23}' + k_{13} + k_{23} + 2k_{33} \\
  k_{13}' & = -2k_{33}' - k_{23}' + \ell_{12} + \ell_{23} + 2\ell_{22} \\
  \ell_{11}' & = k_{33} + \ell_{22} + (K - \ell_{13}) \vee 0 + (-K - k_{12}) \vee 0 \\
  \ell_{22}' & = (K \land k_{11} \land (\ell_{13} - k_{12} - K)) \lor 0 \\
  \ell_{33}' & = (-K \land \ell_{11} \land (k_{12} - \ell_{13} + K)) \lor 0 \\
  \ell_{23}' & = (\ell_{13} \land k_{12} \land (\ell_{13} - K) \land (K + k_{12})) \lor 0 \\
  \ell_{12}' & = -2\ell_{22}' - \ell_{23}' + \ell_{13} + \ell_{23} + 2\ell_{33} \\
  \ell_{13}' & = -2\ell_{33}' - \ell_{23}' + k_{12} + k_{23} + 2k_{22} \\
  t_2' & = \ell_{33} + ((\ell_{13} - \ell_{23} - 2\ell_{22}) \land (K + \ell_{33} - \ell_{22})) \vee 0 + t_2 \\
  t_3' & = -k_{33} + ((L + k_{33}' - k_{22}' \land (k_{13} - \ell_{23} - 2k_{33}')) \land 0 + t_3 \\
  t_4' & = -\ell_{33} + ((K + \ell_{33}' - \ell_{22}) \land (k_{12} - \ell_{23}' - 2\ell_{33}')) \land 0 + t_4 \\
  t_5' & = k_{33} + ((k_{13} - k_{23}' - 2k_{22}')) \land (L + k_{33}' - k_{23}' - k_{22}' - k_{12}) \vee 0 + t_5 \\
  t_1' & = k_{22} + \ell_{22} + k_{33} + \ell_{33} - (\ell_{11}' + k_{11}' + (t_2'-t_2) + (t_5'-t_5)) \\
  & \quad + \text{sgn}(L+K+\ell_{33}'-\ell_{22}'+k_{33}'-k_{23}') (t_1 + \ell_{33}' + k_{33}')
\end{align*}
\]

In these formulas, $K$ is defined to be $k_{11} + t_1$, and $L$ is defined to be $\ell_{11} + t_1$. Furthermore, sgn(0) is defined by the following formula.

\[
\text{sgn}(0) = \begin{cases} 
  +1, & \ell_{12} - 2k_{33}' - k_{23}' \neq 0 \\
  -1, & \text{else}
\end{cases}
\]

Proof: The proof is Step 5, an application of Remark 7.1 and some algebraic manipulation. In fact all the formulas follow immediately.
from Steps 1-4 and Remark 7.1 except those for $\ell_{11}'$ and $k_{11}'$. For these two formulas, we must do some algebraic manipulation.

Consider the expression for $k_{11}'$. One first verifies that

$$k_{22}' + k_{23}' + k_{33}'$$

is equal to the following expression.

$$\begin{cases}
0, L \geq 0 & L \geq k_{13} \\
k_{13} - L, L \geq 0 & k_{13} - \ell_{12} \leq L \leq k_{13} \\
\ell_{12} + (L \Delta \ell_{11} \Delta (k_{13} - \ell_{12} - L)), L \geq 0 & L \leq k_{13} - \ell_{12} \\
0, L \leq 0 & -L \geq \ell_{12} \\
\ell_{12} + L, L \leq 0 & \ell_{12} - k_{13} \leq -L \leq \ell_{12} \\
k_{13} - (L \Delta k_{11} \Delta (\ell_{12} - k_{13} + L)), L \leq 0 & -L \leq \ell_{12} - k_{13}
\end{cases}$$

One then computes that

$$k_{11}' - k_{22}' - \ell_{33}' = (L - k_{13} + Y) \lor 0 + (-L - \ell_{12}' + Y) \lor 0$$

is equal to $(L - k_{13}) \lor 0 + (-L - \ell_{12}) \lor 0$, as desired. The algebra for $\ell_{11}'$ is similar.

Corollary 7.1: The second elementary transformation from the basis $A'$ to the basis $A$ is given by the following formulas.

$$\begin{align*}
\ell_{11}' &= k_{22}' + \ell_{33}' + (L' - k_{13}') \lor 0 + (-L' - \ell_{12}') \lor 0 \\
\ell_{22}' &= (L' \Delta \ell_{11}' \Delta (k_{13}' - \ell_{12}' - L')) \lor 0 \\
\ell_{33}' &= (-L' \Delta k_{11}' \Delta (\ell_{12}' - k_{13}' + L')) \lor 0 \\
\ell_{23}' &= (k_{13}' \Delta \ell_{12}' \Delta (L' - k_{13}') \Delta (\ell_{12}' + L')) \lor 0 \\
\ell_{12}' &= -2\ell_{22}' - \ell_{23}' + k_{13}' + k_{23}' + 2k_{33}' \\
\ell_{13}' &= -2\ell_{33}' - \ell_{23}' + \ell_{12}' + \ell_{23}' + 2\ell_{22}' \\
k_{11}' &= k_{33}' + \ell_{22}' + (K' - \ell_{13}') \lor 0 + (-K' - k_{12}') \lor 0 \\
k_{22}' &= (K' \Delta k_{11}' \Delta (\ell_{13}' - k_{12}' - K')) \lor 0 \\
k_{33}' &= (-K' \Delta \ell_{11}' \Delta (k_{12}' - L' + K')) \lor 0
\end{align*}$$
In these formulas, \( K' \) is defined to be \( k'_{11} + t'_{1} \), and \( L' \) is defined to be \( \ell'_{11} + t'_{1} \). Furthermore, \( \text{sgn}(0) \) is defined by the following formula.

\[
\text{sgn}(0) = \begin{cases} 
+1, & \text{if } \ell'_{12} - 2\ell'_{23} - \ell'_{23} \neq 0, \\
-1, & \text{else}. 
\end{cases}
\]

**Proof:** The symmetry of \( S_2 \) indicated in Figure 7.21 implies that the formulas for \( \ell'' (k''_1) \) are the formulas for \( k''_1 (\ell''_1) \), replacing \( \ell'' (k''_1) \) by \( \ell''_1 (k''_1) \) and \( \ell''_1 (k''_1) \) by \( k''_1 (\ell''_1) \). The formula for \( t''_1 \) is the formula for \( t''_{1''} (\ast'' \sigma^{-1} (\ast'')) \), with the symbol replacement as above and \( t''_{1''} (\ast'' \sigma (\ast'')) \) replacing \( t''_1 \), where \( \sigma \) fixes \( 1 \) and is the cyclic permutation \((2, 4, 5, 3)\) on the other pants curves.

One can of course prove the corollary directly by mimicking the proof of the theorem with \((A', A)\) replacing \((A, A')\). To prove this corollary by checking that the transformations in the corollary and the theorem are inverses (as in Section 6) is a very difficult computation.
rotation by $\pi/2$

second elementary transformation

Figure 7.21
SECTION 8

Having computed the first and second elementary transformations (and their inverses) in the previous two sections, we state the results of Theorems 6.1 and 7.1 here for the convenience of the reader.

Theorem 8.1: The first elementary transformation from the basis $A$ to the basis $A'$ is given by:

\[
\ell_{11}' = (\ell_{12} - |t_1|)\vee 0
\]

\[
\ell_{12}' = (\ell_{13} - (\ell_{12} - \ell_{11}') + \ell_{11}
\]

\[
\ell_{23}' = |t_1| - (\ell_{12} - \ell_{11}')
\]

\[
t_2' = t_2 + \ell_{11}' + ((\ell_{12} - \ell_{11}')dt_1)\vee 0
\]

\[
t_1' = -\text{sgn}(t_1) (\ell_{23} + (\ell_{12} - \ell_{11}')
\]

In these formulas, $\Delta$ denotes the infimum, $\vee$ denotes the supremum, $\text{sgn}$ denotes the sign function, and $\text{sgn}(0)$ is defined to be $-1$.\[\square\]

Theorem 8.2: The second elementary transformation from the basis $A$ to the basis $A'$ is given by:

\[
\ell_{11}' = \ell_{22} + \ell_{33}^1 + (\ell_{12} - \ell_{13}^2)\vee 0 + (-\ell_{12} - \ell_{13}^2)\vee 0
\]

\[
\ell_{22}' = (\ell_{11}^2 + \ell_{12}^2 - \ell_{13}^2)\vee 0
\]

\[
\ell_{33}' = (-\ell_{11}^2 + \ell_{12}^2 + \ell_{13}^2)\vee 0
\]

\[
\ell_{23}' = (\ell_{12}^2 + \ell_{13}^2 - \ell_{12}^1)\Delta (\ell_{13}^1 - \ell_{12}^1)\vee 0
\]

\[
\ell_{12}' = -2\ell_{22}' - \ell_{23}' + \ell_{13}^2 + \ell_{23}^2 + 2\ell_{33}^2
\]

\[
\ell_{13}' = -2\ell_{33}' - \ell_{23}^1 + \ell_{12}^1 + \ell_{23}^1 + 2\ell_{22}^1
\]
\[ \ell_{11} = \ell_{22} + (\ell_{12} - \ell_{13})\nu 0 + (-\ell_{2} - \ell_{12})\nu 0 \]
\[ \ell_{22} = (\ell_{2} \ell_{11} (\ell_{13} - \ell_{12} - \ell_{2}))\nu 0 \]
\[ \ell_{33} = (-\ell_{2} \ell_{11} (\ell_{12} - \ell_{13} + \ell_{2}))\nu 0 \]
\[ \ell_{23} = (\ell_{13} \ell_{12} (\ell_{13} - \ell_{2})) (\ell_{2} + \ell_{12})\nu 0 \]
\[ \ell_{12} = -2\ell_{11} - \ell_{13} + \ell_{13} + 2\ell_{13} \]
\[ \ell_{13} = -2\ell_{11} - \ell_{23} + \ell_{23} + 2\ell_{23} + 2\ell_{22} \]
\[ \ell_{23} = \ell_{23} + ((\ell_{13} - \ell_{23} - 2\ell_{22})\Delta (\ell_{2} + \ell_{13} - \ell_{22}))\nu 0 + \ell_{2} \]
\[ \ell_{33} = -2\ell_{2} + (\ell_{1} + \ell_{2})\nu 0 \]
\[ \ell_{13} = (\ell_{2} + \ell_{13} - \ell_{22})\nu 0 \]
\[ \ell_{13} = (\ell_{13} - \ell_{22})\Delta (\ell_{2} + \ell_{13} - \ell_{22})\nu 0 + \ell_{2} \]
\[ \ell_{13} = \ell_{22} + \ell_{22} + \ell_{22} + \ell_{22} - (\ell_{11} + \ell_{1}) + (\ell_{2} + \ell_{2} + \ell_{2} + \ell_{2}) \]
\[ + \operatorname{sgn}(\ell_{1} + \ell_{2} + \ell_{1} + \ell_{2} - \ell_{22} + \ell_{22} - \ell_{22}) \]
\[ \text{In these formulas, } \Delta \text{ and } \nu \text{ are as in Theorem 8.1, } \ell_{1} \text{ denotes the quantity } \ell_{11} + \ell_{1}, \text{ and } \ell_{2} \text{ denotes the quantity } \ell_{11} + \ell_{1}. \text{ Furthermore, } \operatorname{sgn} \text{ denotes the sign function, and } \operatorname{sgn}(0) \text{ is defined as follows:} \]
\[ \operatorname{sgn}(0) = \begin{cases} +1, & \text{if } \ell_{1} - 2\ell_{2} - \ell_{2} + 0. \\ -1, & \text{else.} \end{cases} \]

These theorems give explicit formulas for the action on \( \mathcal{P}(\mathbb{F}_g) \) of Lickorish's generators for \( \text{MC}(\mathbb{F}_g) \) as described in Section 3. The piecewise-integral character of the action is directly implied by Theorems 8.1 and 8.2. Unfortunately, the formulas are rather cumbersome, insofar as several of the Lickorish generators act as linear maps conjugated by compositions of the elementary transformations.
One's first reaction to the complexity of the situation is panic, and an appropriate response is to write a computer code to perform the algebra of the computations. The formulas of the elementary transformations are particularly amenable to computerization, since they are essentially sums of infs and sups of linear maps. The notable exception to this is the sign that appears in the expression for the twisting number $t_1$ in either transformation.

A FORTRAN code has been written to compute the action of $\text{MC}(F_g)$ on the collection of multiple arcs, as described in this thesis. Several hundred thousand cases of the computation have been run, checking that a transformation followed by its inverse yields the identity in each case. Moreover, many trends predicted by Thurston's theory of surface automorphisms are exhibited by experimenting with this code. (See Subsection 2 below for a brief description of the Thurston theory.) The code is great fun to play with, and a source listing with documentation is contained in Appendix C. (The reader interested in the bookkeeping details of the computation outlined in Section 3 should refer to Appendix C.)

A more optimistic reaction to the complexity of the formulas derived is to begin computing the various compositions that arise in the hopes of simplifications of the sort that occur in the proof of Theorem 7.1. This is not, I think, an unrealistic optimism. The sort of computations that this involves are a rather pleasant blend of combinatorics and linear algebra, and some progress has been made. I will briefly describe some work in this direction.

Consider the pants decomposition shown in Figure 8.1 on the $n$-times punctured sphere, $n > 4$, denoted $S^2 \setminus n\ast$. We distinguish the subgroup
of $\text{MC}(S^2 \setminus \text{n}* \ast)$ corresponding to the homeomorphisms fixing each of the punctures. This subgroup of $\text{MC}(S^2 \setminus \text{n}* \ast)$ is called the pure mapping class group of $S^2 \setminus \text{n}* \ast$, and is denoted $\text{PMC}(S^2 \setminus \text{n}* \ast)$. It is well-known [2] that $\text{PMC}(S^2 \setminus \text{n}* \ast)$ is isomorphic to the pure $n$-braid group on $S^2$ modulo its center. $\text{PMC}(S^2 \setminus \text{n}* \ast)$ is generated by Dehn twists along the nullhomologous curves in Figure 8.2. Just as in Section 3, to compute the action of $\text{PMC}(S^2 \setminus \text{n}* \ast)$ on $\mathcal{G}'(S^2 \setminus \text{n}* \ast)$, it suffices to compute the transformations indicated in Figure 8.3. These transformations are easily derived from the formulas of Theorem 8.2; in fact, the piecewise-integral action of $\text{PMC}(S^2 \text{-minus-n-points-minus-}(4-n)-\text{discs})$ is a restriction of the piecewise-integral action of $\text{PMC}(S^2 \text{-minus-four-discs})$.

![Figure 8.1](image1)

![Figure 8.2](image2)

![Figure 8.3](image3)
For spheres with \( n \) punctures, I have explicitly computed several of the compositions of transformations that arise in the action of \( \text{PMC}(S^2\setminus n\star) \), and there is a concise description of the action in several cases. A particularly simple case is the action of \( \text{PMC}(S^2\setminus 4\star) \) on the subset of \( \mathcal{F}(S^2\setminus 4\star) \) corresponding to (necessarily closed) multiple arcs with no boundary-parallel components. This action is faithfully represented by an action on our parameter values of the group of invertible integral matrices generated by \( \begin{pmatrix} 1 & -2 \\ 0 & -3 \end{pmatrix} \) and \( \begin{pmatrix} 1 & 2 \\ 0 & 1 \end{pmatrix} \).

The action is a twisted right action given by:

\[
(\ell_{11}, t_1) \begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} a\ell_{11} + ct_1 \\ a\ell_{11} + ct_1 \end{pmatrix}, \quad \text{sgn}(a\ell_{11} + ct_1) \begin{pmatrix} b\ell_{11} + dt_1 \\ b\ell_{11} + dt_1 \end{pmatrix}
\]

This description of the action of the pure mapping class group of \( S^2\setminus 4\star \) on the collection described above will be useful in our subsequent discussions of applications.

We will discuss several applications of our computations in turn in the following five subsections. When convenient, we will assume our surfaces are supplied with a fixed smooth structure.

1) The Word Problem for Lickorish's Generators of \( \text{MC}(F_g) \)

Using the Alexander trick, one easily proves the following Proposition.

**Proposition 8.1:** Let \( \psi \) be a mapping class on \( F_g \), and let \( \{c_k\} \) be a collection of simple closed curves so that

a) \( F_g \cup \{c_k\} \) consists of discs.

b) \( c_k \cap c_{k'} \) is either empty or a single transverse intersection, for \( k \neq k' \).

\( \psi \) is the identity in \( \text{MC}(F_g) \) if and only if \( \psi \) fixes the isotopy class of each \( c_k \).

\( \blacksquare \)
Thus, the computations of this thesis give an efficient algorithm for solving the word problem for Lickorish's generators of $\text{MC}(F)$: one simply evaluates a given word on some collection $\{c_k\}$ as in Proposition 8.1 and checks that the isotopy class of each $c_k$ is fixed.

It is well-known \textsuperscript{(21)} that $\text{MC}(F)$ is isomorphic to the group of "orientation-preserving" outer automorphisms of $\pi_1(F)$. Thus, a mapping class is the identity in $\text{MC}(F)$ if and only if each of its representatives acts like an inner automorphism of $\pi_1(F)$. This could be regarded as giving an "algorithm" for the word problem in Lickorish's generators: one checks that the word acts like an inner automorphism on a set of generators for $\pi_1(F)$. This is an unwieldy computation for words of large length.

Isotopy classes are the same as free homotopy classes of curves embedded in surfaces \textsuperscript{[7]}; furthermore, free homotopy classes of curves are the same as conjugacy classes in $\pi_1(F)$ modulo orientation. Thus, our formulas describe the action of Lickorish's generators on embedded conjugacy classes in $\pi_1(F)$ modulo orientation.

2) Thurston's Classification of Surface Automorphisms

Let $F$ be a surface of negative Euler characteristic. We will say that a mapping class $\psi$ on $F$ is \textbf{pseudo-Anosov} if, for every iterate $\psi^n$ and for every free homotopy class $[\gamma]$ of non-boundary-parallel, not necessarily embedded connected curve, $[\psi^n \gamma] \neq [\gamma]$. (Note that some iterate of $\psi$ always fixes all boundary-parallel curves.) We will say $\psi$ is \textbf{periodic} if some iterate $\psi^n$ is the identity in $\text{MC}(F)$. We will say $\psi$ is \textbf{reducible} if there is a closed multiple arc $\alpha$, no component of which is boundary-parallel, so that $\psi$ permutes the components of $\alpha$. $\alpha$ is called a \textbf{reducing curve} for $\psi$. 
Simply stated, Thurston's classification says that a mapping class is one of periodic, pseudo-Anosov or reducible. A mapping class may be both periodic and reducible, and this is the only overlap in the classification. A natural problem is the classification of words in Lickorish's generators into periodic, reducible and pseudo-Anosov mapping classes.

The periodic, pseudo-Anosov or reducible character of a mapping class $\psi \in \text{MC}(F)$ has a natural description in terms of its piecewise-integral action on $\mathcal{P}_A(F)$. For instance, suppose that $\psi$ fixes a curve whose parameter values lie in a top-dimensional simplex $\sigma$ of the decomposition $K_\psi$ of the piecewise-integral structure. Under these conditions, there is an eigenvector in $\mathcal{P}_A'(F_\psi)$ with eigenvalue 1 for the integral matrix which corresponds to $\sigma$ in the piecewise-integral structure of the action of $\psi$.

One reason that this problem is of interest is that one can often find a description of the monodromy of a fibred link in terms of Dehn twists, and the periodic, reducible or pseudo-Anosov character of the monodromy is connected with geometrical structures on the link complement. In many examples, the monodromy is the lift of some map to a branched cover of the disc; hence the action of $\text{MC}(S^2 \setminus n^*)$ on $\mathcal{P}'(S^2 \setminus n^*)$ is of interest here.

Another reason that this classification problem is of interest pertains to the following theorem, which will be proved elsewhere [15].

**Theorem 8.3:** Let $\gamma$ and $\delta$ each be multiple curves in a surface $F$ with negative Euler characteristic. Let $\{c_i\}$ and $\{d_j\}$ be the components of $\gamma$ and $\delta$, respectively. Furthermore, assume the two conditions below.
a) $c_i$ and $d_j$ intersect minimally, for all $i$ and all $j$.

b) The components of $F \setminus \bigcup (\{c_i\} \cup \{d_j\})$ are all discs.

Let $w$ be any composition of the Dehn twists $\tau_{c_i}^+$ and $\tau_{d_j}^-$ so that, for each $c_i$ or $d_j$, $\tau_{c_i}^+$ or $\tau_{d_j}^-$ appears at least once in $w$. Under these conditions, $w$ represents a pseudo-Anosov mapping class.

This recipe for constructing pseudo-Anosov mapping classes generalizes known constructions of such. I can prove that this recipe gives all pseudo-Anosov mapping classes in a few cases, and I conjecture that this is true for $g$-holed tori, at least up to iteration of the map and composition with maps of finite order.

For the special case of a mapping class $\psi$ on $S^2 \setminus 4^*$, there is some iterate $\psi^n$ of $\psi$ that is a pure mapping class. The periodic, reducible or pseudo-Anosov character of $\psi$ is determined by the trace of the matrix corresponding to $\psi^n$. (See Proposition 8.2.)

3) The Action of $\text{MC}(F_g)$ on Thurston's Boundary for Teichmuller Space

The Teichmuller space of $F_g$, denoted $\mathcal{T}(F_g)$, is defined to be the space of Riemannian metrics (with the natural topology) of constant curvature $-1$, modulo push-forward by diffeomorphisms isotopic to the identity.

0. Teichmuller [16] showed that $\mathcal{T}(F_g)$ is homeomorphic to an open $6g-6$ disc.

There are several classical compactifications of $\mathcal{T}(F_g)$, and Thurston [17] has given a beautiful compactification of $\mathcal{T}(F_g)$ by a $6g-7$ sphere. We will presently describe Thurston's compactification.

By an $n$-gon in a surface $F$ we mean a smoothly embedded open disc in the interior of $F$, with piecewise smooth frontier and $n$ discontinuities in the tangent of the bounding curve. Some examples of $n$-gons are pictured in Figure 8.4. A subspace $X \subset F$ is said to have a complementary $n$-gon if some component of $F \setminus X$ is an $n$-gon in $F$; $X$ is said to have a complementary annulus if the closure of some component of $F \setminus X$ is a smooth annulus in $F$. 
A train track $T$ in the surface $F$ is a closed branched one-submanifold embedded in $F$, so that $T$ has no complementary null-gons, mono-gons, bi-gons or annuli. Some examples of train tracks are pictured in Figure 8.5. A train track $T$ is a one-complex in a natural way; the 0-simplexes are called the branch points of $T$, and the 1-simplexes are called the branches of $T$. A train track $T$ in $F$ is said to be \textit{transversely recurrent} if, for each branch $b_i$ of $T$, there is a simple closed curve $d$ intersecting $b_i$ transversely in a point; furthermore, there are no bi-gons complimentary to $dVT$. Transverse recurrence is a technical condition that we will require shortly.
A measure $m$ on a train track is an assignment of a positive real number $m(b_i)$ to each branch $b_i$ of the train track $T$. The number $m(b_i)$ is called the weight of the branch $b_i$. The weights are required to satisfy a single relation for each branch point; for instance, whenever the branches $b_i$, $b_j$, and $b_k$ are as indicated in Figure 8.6, the weights must satisfy $m(b_i) = m(b_j) + m(b_k)$. We require an analogous additivity relation when more than three branches have a branch point in common. A measured train track is a natural generalization of a closed multiple arc: closed multiple arcs correspond to measured train tracks with integral weights.

![Figure 8.6](image)

Let $c$ be a simple closed curve in $F_g$, and let $(T, m)$ be a measured train track. Isotope $c$ so that it misses the branch points of $T$ and there are no $b_i$-gons complementary to $c \cup T$. If $\text{card}(c \cap b_i) = t_i$, we define the length of $c$ to be $\sum t_i m(b_i)$. The length of the isotopy class of $c$ is well-defined, and we extend the definition of length to closed multiple arcs by requiring length to be additive on components.

We will say that two measured train tracks are equivalent if they
define the same length function on closed multiple curves. Two measured train tracks with length functions $L_1$ and $L_2$ are said to be projectively equivalent if there is some positive real number $r$ so that $L_1 = rL_2$. Thurston [17] shows that the collection of projective equivalence classes of transversely recurrent train tracks (with a suitable topology) forms a $6g-7$ sphere that compactifies $\mathcal{T}(F_g)$.

$\text{MC}(F_g)$ acts on $\mathcal{T}(F_g)$ by push-forward of metrics, and this action extends to the natural action on Thurston’s boundary: the action of $\text{MC}(F_g)$ on (isotopy classes of) measured train tracks. Our computations describe the action of $\text{MC}(F_g)$ on standard (see Construction 5.1) measured train tracks, and it seems almost certain that any measured train track is projectively equivalent to a standard one. In any case, the collection of (projective equivalence classes of) measured train tracks with integral measures is dense in Thurston’s boundary for $\mathcal{T}(F_g)$; thus, we have already computed the action of $\text{MC}(F_g)$ on a dense subset of Thurston’s boundary for $\mathcal{T}(F_g)$.

4) Linear Representations of Mapping Class Groups.

Let $F$ be some surface. The goal is to exhibit a faithful representation of $\text{MC}(F)$ as a group of invertible matrices or prove that such a representation cannot exist. Such representations would be useful in better understanding the mapping class groups.

We have derived a faithful representation of $\text{MC}(F)$ as a group of piecewise-integral transformations provided the Euler characteristic of $F$ is negative. Furthermore, we have remarked previously that the pure mapping class group of $S^2\setminus 4*$ admits a faithful representation as a subgroup of $\text{SL}_2\mathbb{Z}$. It was mentioned that this action is twisted. Using the results of this thesis, one might hope for analogous twisted linear representations of the pure mapping class groups of $S^2\setminus n*$, $n \geq 4$. It
is possible that our formulas even describe such a representation as they stand, but the twisting in the action renders this unrecognizable.

5) **Dynamics of Surface Homeomorphisms**

Suppose that \( f \) is a homeomorphism from the open two-disc \( D^2 \) to itself, and suppose that \( x \) is a periodic point of \( f \) of period \( n \geq 3 \). Let \( O(x) \) denote the orbit \( \{x, f^1x, \ldots, f^{n-1}x\} \). \( f \) restricts to a homeomorphism of \( D^2 \setminus O(x) \), and we may consider the mapping class of this homeomorphism. Identifying \( D^2 \setminus O(x) \) with \( S^2 \setminus (n+1) \ast \), this mapping class is given by a coset of the (full) \( (n+1) \)-braid group of \( S^2 \) by its center. We will call this coset the **topological type** of \( f \) with respect to the orbit \( O(x) \). The topological type of \( f \) varies from one periodic orbit to another, yet there is an obvious compatibility between topological types of \( f \) with respect to various orbits.

The reason that our computations are applicable is that we can compute topological types. The topological type of \( f \) with respect to \( O(x) \) is determined by its action on \( \mathcal{P}(D^2 \setminus O(x)) \). Note that the topological type of \( f^n \) with respect to \( O(x) \) is a pure mapping class. In fact, we can determine the topological type of \( f^n \) with respect to \( O(x) \) by computing its action on a finite collection of simple closed curves in \( D^2 \). (One proves an analogue of Proposition 8.1.)

More crudely, one may simply consider whether the topological type of \( f \) with respect to \( O(x) \) is periodic, pseudo-Anosov or reducible. There is evidence [4] to suggest that the existence of orbits of certain periods puts restrictions on which of periodic, pseudo-Anosov or reducible topological types can occur.

In the case of period three points, we can use the representation of \( \text{PMC}(S^2 \setminus 4 \ast) \) described above to prove the following proposition.
Proposition 8.2: Suppose $f^o_2 + D^2_2$ is a homeomorphism of the open two-disc, and suppose the $x \in D^2_2$ is a period three point. The topological type $\psi \in PMC(S^2\{4\})$ of $f^3$ with respect to the orbit of $x$ is described by an invertible two-by-two integral matrix $B$. $B$ is determined by the action of $f^3$ on two simple closed curves in $D^2_2$. Moreover,

a) $\psi$ is reducible if and only if $|\text{tr}B| = 2$.

b) $\psi$ is periodic if and only if $|\text{tr}B| \leq 2$.

c) $\psi$ is pseudo-Anosov if and only if $|\text{tr}B| \geq 2$.

In conclusion, there are many interesting problems associated with the action computed herein. What is lacking as a good qualitative understanding of the formulas that we have derived. The setting in which to begin developing this understanding is the setting of punctured spheres, and some progress has been made in this direction.
APPENDIX A

In this appendix, we prove several technical results about symbols that are used in Sections 6 and 7. We adopt the notation of Sections 6 and 7.

Proposition A.1: Let B and B' be two bases on the standard pants P that differ only in the choice of canonical piece \(1_{11}\) or \(\hat{1}_{11}\) (see Section 2). The transformation between \(\mathcal{P}_B'(P)\) and \(\mathcal{P}_B''(P)\) is described by the following formula.

\[
(m_1, m_2, m_3) \times (t_1, t_2, t_3) + (m_1, m_2, m_3) \times (t_1 \pm \ell_{11}, t_2, t_3)
\]

Proof: The simple and very useful isotopy that proves this proposition is indicated in Figure A.1. \(\Box\)
Proposition A.2: If $s_{1}^{n_{1}}$ and $s_{2}^{n_{2}}$ both occur as sub-symbols of (some components of) an embedded admissible symbol, where $|n_{1}|$ and $|n_{2}|$ are maximal, then $|n_{1} - n_{2}| \leq 1$.

Proof: Let $t^{m}$ denote an arc twisting $m$ times in the standard annulus $A$; $A_{1} \setminus v_{1}^{-1}t_{1}$ is a disc in which $v_{1}^{-1}t_{2}$ is a properly embedded arc.\(\checkmark\)

Corollary A.1: If $s_{1}^{n_{1}}$ and $s_{2}^{n_{2}}$ both occur as sub-symbols of (some components of) an embedded admissible symbol, then $\text{sgn}(n_{1}) = \text{sgn}(n_{2})$, provided $n_{1} \neq 0 \neq n_{2}$.\(\checkmark\)

Proposition A.3: a) If $s_{1}^{-1}s_{11}^{+}$ occurs as a sub-symbol in some embedded admissible $A$-symbol $s$ on $S_{2}$, then an $s_{11}^{+}$ in $s$ is always followed by a $s_{1}^{-1}$.

b) If $s_{1}^{-1}s_{11}^{+}$ occurs as a sub-symbol in some embedded admissible $A$-symbol $s$ on $S_{2}$, then an $s_{11}^{+}$ in $s$ is always followed by a $s_{1}^{-1}$.

Proof: These are the only embedded possibilities as indicated in Figure A.2.\(\checkmark\)
Proposition A.4: a) The image of $s_{11}^{\pm} st_{1}^{-1}$ in an A-symbol on $S_2$ under the combinatorial homotopy without boundary effects in Section 7 is $st_{1}^{-1}s_{11}^{\pm}$.

b) The image of $sk_{11}^{\pm} st_{1}^{-1}$ in an A-symbol on $S_2$ under the combinatorial homotopy without boundary effects in Section 7 is $st_{1}^{-1}sk_{11}^{\pm}$.

Proof: In Figure A.3, we illustrate the combinatorial homotopy in $S_2$ for cases a) and b). We use the results of Proposition A.3 to guarantee that the lifts are as indicated in Figure A.3. The solid lines indicate the lifts, and the broken lines indicate the image of the homotopy.
APPENDIX B

In this appendix, we check by hand the formulas for the two elementary transformations on connected, non-exceptional $A$-symbols of $A$-length less than five. There are several special cases here that we wished to avoid in the combinatorial arguments of Sections 6 and 7. Since these special cases all have small $A$-length, it seems easiest to exhaustively check these few cases.

These computations are a good exercise for the reader wishing to familiarize him or herself with the parametrizations in Section 2 and the bases used in Sections 6 and 7.

For the first elementary transformation, there are six cases. In the following diagrams, we indicate the $A$-coordinates and depict a good representative on the left; on the right, we give the same data for the basis $A'$. We omit mention of any parameter values that are equal to zero.
\[ s_{12} \quad s_{12}^{-1} \quad s_{13} \quad s_{13}^{-1} \quad s_{13} \quad s_{12}^{-1} \quad s_{13}^{-1} \quad s_{13} \]

\[ m_2 = 2, \quad m_1 = 1, \quad t_1 = -2 \]

\[ s_{12}^t \quad s_{12}^t \quad s_{12}^t \quad s_{13} \quad s_{13}^t \quad s_{13} \quad s_{12}^{-1} \quad s_{13}^{-1} \quad s_{13} \]

\[ m_2 = m_1 = 2, \quad t_1 = 1 \]

\[ s_{12}^t \quad s_{12}^t \quad s_{12}^t \quad s_{13} \quad s_{13}^t \quad s_{13} \quad s_{12}^{-1} \quad s_{13}^{-1} \quad s_{13} \]

\[ m_2 = m_1 = 2, \quad t_1 = 1 \]

\[ s_{12}^t \quad s_{12}^t \quad s_{12}^t \quad s_{13} \quad s_{13}^t \quad s_{13} \quad s_{12}^{-1} \quad s_{13}^{-1} \quad s_{13} \]

\[ m_2 = m_1 = 2, \quad t_1 = 1 \]
For the second elementary transformation, we check eight cases of $A$-length three and seven cases of $A$-length four. We use the symmetry of rotation-by-$\pi$ about the line $l$ in Figure B.1 to avoid considering cases whenever possible. Moreover, in case of $A$-length four, we do not consider multiple arcs with $|t_1| = 2$ since the considerations of Section 7 apply to this setting.

In the following diagrams, we indicate the $A$-coordinates and depict a good representative on the left; on the right, we give the same data.
for the basis $A'$. We omit mention of any parameter values that are equal to zero.

APPENDIX C

CONTROL USLIMIT,NOSOURCE
PROGRAM TWIST

This code performs the computation of the action
of mapping classes on curves and arcs in closed
oriented surfaces as described in my thesis. The
parametrization of curves and arcs depends on
various choices, including the choice of a pants
decomposition of the surface. The standard pants
decompositions are indicated by the curves numbered
1,...,3*GENUS-3 in figure 1. I refer to my thesis
for the other choices of
convention required for a parametrization. Briefly,
the conventions are that zero intersection
number implies non-negative twisting number, and
arcs in the standard pants running from a component
of the boundary back to the same component loop
around to the right.

We consider the action of Dehn twists along
the 5*GENUS-4 curves pictured in figure 1. These
are of four geometrical types:
1) Twists along a pants curve
2) Twists along a curve in the torus minus
two discs intersecting two pants curves
3) Twists along a curve in the torus minus
one disc intersecting one pants curve
4) Twists along a curve in the sphere minus
four discs intersecting one pants curve.
The curves in figure 1 are numbered so that
twists 1,...,3*GENUS-3 are of type 1, twists
3*GENUS-2,...,4*GENUS-5 are of type 2, twists
4*GENUS-4 and 4*GENUS-3 are of type 3, and
twists 4*GENUS-2,...,5*GENUS-4 are of type
4. In genus 2, twists 1,2 and 3 are of type
1 and twists 4 and 5 of type 2.

The code prompts the user for the input
data as will be explained, and the dimensions
of arrays are set to handle genera 2,3 and 4.
To set dimensions for higher genera, one needs
only change the first dimension of the array
NCURVE in main and the data value of MARDIM
3*GENUS-3.

NCURVE holds the parameter value of the
curve under consideration at any given stage of
the computation. At various points, this parameter
value is relative to various pants decompositions,
and we store only one set of parameters at a time.
Thus, when calling one of the elementary
transformations, NCURVE holds the parameter values
relative to a certain pants decomposition, and
upon return from one of the elementary transformations,
NCURVE holds the parameter values relative to a
different pants decomposition.

C
C PROMPT THE USER FOR THE GENUS OF THIS RUN.
C
C WRITE(6, 56)
C ACCEPT NGENUS
C NDIM=3*NGENUS-3
C
C PROMPT THE USER FOR THE COORDINATES OF THE CURVE
C OR ARC UNDER CONSIDERATION. THE COORDINATES ARE
C GIVEN BY A (3+GENUS-3)-TUPLE OF (INTERSECTION
C NUMBER, TWISTING NUMBER), AND THE PANTS CURVES
C ARE NUMBERED AS IN FIGURE 1.
C
C 99 WRITE(6, 57)
C ACCEPT (NCURVE(I, J), J=1, 2), I=1, NDIM
C
C PROMPT THE USER FOR THE NUMBER OF LETTERS IN THE
C WORD UNDER CONSIDERATION. THE MAXIMUM WORD LENGTH
C IS 25 LETTERS.
C
C WRITE(6, 58)
C ACCEPT NTWIST
```
Prompt the user for the word. Words are read from left to right, and are given by a (NTWIST)-tupple of (CURVE NUMBER, EXPONENT), where NTWIST is the number of letters in the word.

**Prompt the user for the word. Words are read from left to right, and are given by a (NTWIST)-tuple of (CURVE NUMBER, EXPONENT), where NTWIST is the number of letters in the word.**

```
WRITE(6,59) ACCEPT ((NTAV(I,J),J=1,2),I=1,NTWIST)
```

This is the main loop over the letters in the word. The geometrical type of the letter is determined, and the call to the appropriate subroutine is made.

```
DO 100 I=1,NTWIST
   NTAU=NTAV(I,1)
   NEXP=NTAV(I,2)
   IF(NTAU.LE.NDIM) CALL TWIST1(NTAU,NEXP,MXDIM,NCURVE)
   IF(NTAU.LE.4*NGENUS-5.AND.NTAU.GE.3*NGENUS-2) OR. (NGENUS.EQ.2.AND. (NTAU.EQ.4.OR.NTAU.EQ.5) ) CALL TWIST2(NTAU,NEXP,MXDIM,NCURVE)
   IF(NTAU.EQ.4*NGENUS-4.OR.NTAU.EQ.4*NGENUS-3) CALL TWIST3(NTAU,NEXP,MXDIM,NCURVE)
```

Output the coordinates of the image curve as a (3*NGENUS-3)-tuple of (INTERSECTION NUMBER, TWISTING NUMBER).

```
WRITE(6,55) (I,NCURVE(I,J),J=1,2),I=1,HDIM
```

Prompt the user for the next operation. There are three options: STOP, ITERATE, OR CONTINUE. The STOP option ends the run. The ITERATE option applies the word previously entered to the image of the curve under the previous application of this word. The CONTINUE option allows the user to perform a new computation, and the user will be prompted for the coordinates and the word, as before. Note that the CONTINUE option assumes the same genus as the previous computation.
