MODAL ANALYSIS AND CONTROL
OF FLEXIBLE MANIPULATOR ARMS

Octavio Maizza Neto

Submitted to the Department of Mechanical Engineering
on September 10, 1974 in partial fulfillment of the
requirements for the Degree of Doctor of Philosophy

ABSTRACT

This study examines the possibility of modeling and control of
flexible manipulator arms. A modal approach is used throughout the work
for obtaining the mathematical model and control techniques applied. The
arm model is represented mathematically by a state space description de-
dined in terms of joint angles and mode amplitudes obtained from trunc-
ation on the distributed systems, and includes the motion of a two link
two joint arm.

The problem of controlling the system is examined via the linearized
model and using a regulator type of control. Three basic techniques are
used for this purpose: pole allocation with gains obtained from the rigid
system with interjoint feedbacks, Simon-Mitter algorithm for pole allo-
cation and sensitivity analysis with respect to parameter variations.
An improvement in arm bandwidth is obtained that could replace more con-
servative designs currently in use.

Optimization of some geometric parameters is undertaken in order to
maximize bandwidth for various payload sizes and programmed tasks.

The controlled system is examined under constant gains and using the
nonlinear model for simulations following a time varying state trajectory.
The procedure presented in this work is general and can be implemented to
be used in more specific designs.

THESIS SUPERVISOR: Professor Daniel E. Whitney

TITLE: Associate Professor of Mechanical Engineering
ACKNOWLEDGEMENTS

The author wishes to express his appreciation to those who have been of great help in the preparation of this thesis. Professor Daniel E. Whitney has been a very helpful committee chairman. He has spent much time in consultation, and has provided valuable suggestions. The author is also grateful to Professor Leonard A. Gould, Professor Richard S. Sidell and Professor James H. Williams, Jr, for their valuable help both in committee meetings and in private consultation. For their valuable discussions on the thesis topic the author is indebted to Dr. Wayne J. Book, Mr. Sergio Simunovic and Mr. Jaime Szajner, as well as other members of the graduate student body.

Particular acknowledgement goes to my wife, Norma, for her valuable non-technical support at home, through four years leading to the completion of this degree. Sincere thanks also to my parents for providing moral support in earlier education.

The efficient staff of Joint Computer Facility, Civil-Mechanical Engineering has been of great help in programming and debugging. Special thanks go to Mr. Larry Hare and Mr. Stanley Knutson for their time and energy devoted to this good cause.

Appreciation is expressed to Alice J. Sanderson who typed this thesis with its several equations.

This research was supported in part by Fundação de Amparo a Pesquisa do Estado de São Paulo, Brazil, Escola Politécnica da Universidade de São Paulo, Brazil, and George C. Marshall Space Flight Center, contract number NAS8-28055.

CHAPTER I
INTRODUCTION

1.1 Scope of the Work

Many recent studies deal with the design and control of mechanical manipulators that perform tasks similar to those of human arms. The possibility of using small computers located in the vicinity of the manipulator originated the so-called supervisory controlled devices, especially important when the distance between the arm and the operator introduces a time lag in the information process [N2], [T1]. However, the arm dimensions or the velocity of performing a task can increase the effects of nonlinear factors that will complicate even more the control process. Such control procedures would require nonlinear techniques that may not be at hand. In the case of flexible mechanical arms, the vibrations originated by the elasticity of the links would affect the effectiveness of the system and even cause instability. In the interest of reducing these vibrations, this study deals with the control of the nonlinear system with results obtained from the linear control theory. A suitable mathematical model is developed to represent the plane motion of two flexible beams by considering the rigid and flexible motions. The hypothesis of controlling the dynamic motion of the nonlinear model is examined by means of modal control applied to the linearized model.

1.2 The System Mathematical Description

The approach assumed in this work is to derive the equations of motion of a system of two flexible beams pinned at one end and at the
joint. Lagrange's equation applied to a distributed system are used for this purpose. Basically the model is obtained by superposing the flexible motion over a hypothetical rigid body motion. For the purpose of this study, the elastic motion of the beams is truncated in the second mode and a six degree of freedom, nonlinear model is obtained. A good approximation for the dynamic shapes of the beams during the motion is achieved by using the appropriate boundary conditions. Some experimental results have shown good approximations for the values of natural frequencies of the uncontrolled system when compared with those obtained from the linearized mathematical model. Details of these procedures can be found in Chapter II.

1.3 Control from the Perspective of Manipulator Design

The basic idea for controlling the system is to find the forces of torques that must be exerted on the manipulator joints in order to move the system from its present configuration to the desired position. If fast motions have to be performed, the dynamic forces will become significant and a reasonable control must be achieved for the nonlinear system. On the other hand, slow motion with large payload might give rise to undesired large deflections of the links.

A broad analysis of manipulator design would depend upon geometric and elastic parameters, according to the tasks to be performed. In this work one considers the implications of applying modal control techniques to either short and rigid manipulators such as automation devices or long and flexible ones like the space shuttle boom. In both cases,
the control performance would depend upon physically available measurements. However, only a limited number of these quantities might be obtained for a given arm configuration. This suggests the comparison of control performance for cases where all of the variables could supposedly be measured and those when only some of them are available. Three different techniques are used in the present work resulting in a linear regulator type of control. The first technique works with the gains obtained in the allocation of poles in the rigid equivalent system and uses those gains in the control of the flexible model. The convenience of this method is accentuated by the fact that simple measurements are sufficient for controlling the system. The second procedure is the use of Simon-Mitter algorithm [S1], [S2] for independent positioning of poles. This procedure requires the measurement and/or estimation of some state variables that might require very sophisticated instruments. Finally, the third method makes use of the poles sensitivities with respect to parameters variations in order to find the elements of the feedback law. These procedures are described in Chapter III and a comparison of results is presented in Chapter IV. Estimates of maximum arm bandwidth are presented for the case of controlling the flexible system with a control law obtained from the rigid model.

Some simulations of the nonlinear system using the rigid control law and Simon-Mitter algorithm are presented in Chapter V for analyzing the system performance in tracking a time varying state trajectory.
1.4 Remarks

The study of controlling flexible manipulators was first undertaken by Mirro [M2] in which a single beam is analyzed from the point of view of optimal regulator theory. Before that, Townsend [T1], Kahn [K1] and many others were concerned with controlling essentially rigid manipulator arms. The most recent work on flexible systems is presented by Book [B2] and Whitney, Book, Lynch [W2] where the pertinent literature can be found.
CHAPTER II

SYSTEM DESCRIPTION

2.1 The Physical Model

The schematic of the general physical system is shown in Figure 2.1. The system is composed of two flexible bodies connected by a frictionless pinned joint. One end of the system is attached to the origin of a reference frame. The system is assumed to have planar motion and the relative motion of the two bodies results from torques applied at each joint of the system. In order to facilitate the description, the joints are numbered by 1 and 2 and the bodies will be represented by two flexible beams. At the end of beam 1, a concentrated mass representing the servo-motor at joint 2 and the joint itself; at the end of beam 2, a discrete mass can also appear, representing a payload to be moved between two points in the plane.

In order to describe the motions, three reference frames can be defined:

\[[0,x,Y] - an\ initial\ reference\ frame\ with\ origin\ at\ joint\ 1\]

\[[0,x_1y_1] - a\ reference\ frame\ with\ origin\ at\ 0\ and\ the\ axis\ x_1\ tangent\ to\ beam\ 1\ at\ point\ 0\]

\[[0_2,x_2,y_2] - a\ reference\ frame\ with\ origin\ at\ joint\ 2\ and\ with\ axis\ x_2\ tangent\ to\ beam\ 2\ at\ point\ 0_2\]

Also two angles can be defined:

\[\theta_1(t)\ is\ the\ angle\ between\ the\ axes\ x_1\ and\ X\]

\[\theta_2(t)\ is\ the\ angle\ between\ the\ axes\ x_1\ and\ x_2\]
If now a new system is defined as being formed by two segments $0O_1$ and $O_1O_3$, having the angle $\theta_2$ at $O_1$, the overall motion can be understood as a motion of a hypothetical rigid system $0O_1O_3$ and a flexible motion of the beams 1 and 2 with respect to this moving system. In order to simplify the notations a matrix representation form of the reference frames can be introduced.

Let

$$\{\tilde{U}\} = \begin{bmatrix} \tilde{u}_x \\ \tilde{u}_y \end{bmatrix}$$

be the unit vector of reference frame $OXY$.

$$\{\tilde{U}_1\} = \begin{bmatrix} \tilde{u}_{x1} \\ \tilde{u}_{y1} \end{bmatrix}$$

the unit vector of reference frame $Ox_1y_1$.

$$\{\tilde{U}_2\} = \begin{bmatrix} \tilde{u}_{x2} \\ \tilde{u}_{y2} \end{bmatrix}$$

the unit vector of reference frame $Ox_2y_2$.

then

$$\{\tilde{U}_1\} = [C_1] \{\tilde{U}\} \quad (2.1.1)$$

$$\{\tilde{U}_2\} = [C_2] \{\tilde{U}\} \quad (2.1.2)$$

$[C_1]$ and $[C_2]$ are the rotational-transformation matrices. (Reference $[C2]$).

\]  

(2.1.10)
Vector Position of One Element in Beam 1

Figure 2.2
2.2 Kinematic Description

The position of any point in the system can be described by a convenient definition of a set of coordinates. As indicated in Figure 2.2, any point $P_i$ can be specified if a new variable $u_i(x_i,t)$ is defined as being the coordinate of the flexible motion with respect to the reference frame $[0_1x_1y_1]$. The vector position of point $P_i$ would be

$$\vec{R}_{di} = \{\vec{U}_i\}^t \begin{bmatrix} x_i \\ y_i \end{bmatrix} = x_i \vec{u}_x + y_i \vec{u}_y$$  \hspace{1cm} (2.2)

2.2.1 Beam 1

The vector position of any point in beam 1 is

$$\vec{R}_{d1} = \{\vec{U}_1\}^t \begin{bmatrix} x_1 \\ u_1 \end{bmatrix} = \{\vec{U}\}^t \begin{bmatrix} C_1 \end{bmatrix}^t \begin{bmatrix} x_1 \\ u_1 \end{bmatrix} = (x_1 c_\theta - u_1 s_\theta) \vec{u}_x$$

$$+ (x_1 s_\theta + u_1 c_\theta) \vec{u}_y$$  \hspace{1cm} (2.3)

2.2.2 Beam 2

In order to define the vector position of any point on beam 2, it will be necessary to assume that the displacements of the flexible bodies with respect to reference frames $[0x_1y_1]$ and $[0_2x_2y_2]$ be small enough to consider the paths of points $O_2$ and $O_p$ as straight lines normal to the respective reference frames. Then, as shown in Figure 2.3,
the vector position of any point $P_2$ on beam 2 will be

Vector Position of one Element in Beam 2

Figure 2.3
\[ \vec{R}_{d2} = \vec{0}_{01} + \vec{0}_{12} + \vec{0}_{2P_2} + \vec{P}_2 \cdot \vec{p}_2 \]  \hspace{1cm} (2.4)

If now

\[ u_{1E} = \text{flexible linear displacement at end of beam 1} \]

\[ l_1 = \text{length of beam 1} \]

\[ l_2 = \text{length of beam 2} \]

then

\[ \vec{0}_{01} = (\vec{u})^t \begin{Bmatrix} l_1 c \theta_1 \\ -l_1 s \theta_1 \end{Bmatrix} = l_1 c \theta_1 \vec{u}_x + l_1 s \theta_1 \vec{u}_y \]  \hspace{1cm} (2.5.1)

\[ \begin{Bmatrix} \vec{0}_{12} \end{Bmatrix} = (\vec{u})^t \begin{Bmatrix} -u_{1E} s \theta_1 \\ u_{1E} c \theta_1 \end{Bmatrix} = -u_{1E} s \theta_1 \vec{u}_x + u_{1E} c \theta_1 \vec{u}_y \]  \hspace{1cm} (2.5.2)

\[ \vec{0}_{2P_2} = (\vec{u})^t \begin{Bmatrix} \frac{x_2}{0} \end{Bmatrix} = (\vec{u})^t [\mathbf{C}_1]^t \begin{Bmatrix} \frac{x_2}{0} \end{Bmatrix} = x_2 c(\theta_1 + \theta_2) \vec{u}_x + x_2 s(\theta_1 + \theta_2) \vec{u}_y \]  \hspace{1cm} (2.5.3)

\[ \vec{P}_2 \cdot \vec{p}_2 = (\vec{u})^t \begin{Bmatrix} 0 \\ \vec{u}_2 \end{Bmatrix} = (\vec{u})^t [\mathbf{C}_2]^t \begin{Bmatrix} 0 \\ \vec{u}_2 \end{Bmatrix} = -u_2 s(\theta_1 + \theta_2) \vec{u}_x + u_2 c(\theta_1 + \theta_2) \vec{u}_y \]  \hspace{1cm} (2.5.4)
and

\[
\vec{R}_{d_2} = \{\vec{U}\}^t \left[ \begin{array}{c}
l_1 c\theta_1 \\
l_1 s\theta_1
\end{array} \right] + \left[ -u_1 Es\theta_1 \right] + \left[ C_1 \right]^t \left[ \begin{array}{c}x_2 \\
0
\end{array} \right] + \left[ C_2 \right]^t \left[ \begin{array}{c}0 \\
u_2
\end{array} \right]
\]

(2.6.1)

\[
\vec{R}_{d_2} = [l_1 c\theta_1 - u_1 Es\theta_1 + x_2 c(\theta_1 + \theta_2) - u_2 s(\theta_1 + \theta_2)]\vec{u}_x
\]

\[
+ [l_1 s\theta_1 + u_1 Ec\theta_1 + x_2 s(\theta_1 + \theta_2) + u_2 c(\theta_1 + \theta_2)]\vec{u}_y
\]

(2.6.2)

The respective velocities are

\[
\vec{R}_{d_1} = [-\dot{\theta}_1 x_1 s\theta_1 - \dot{u}_1 s\theta_2 - \dot{\theta}_1 u_1 c\theta_1]\vec{u}_x + [\dot{\theta}_1 x_1 c\theta_1 + \dot{u}_1 c\theta_1 - u_1 \dot{\theta}_1 s\theta_1]\vec{u}_y
\]

(2.7)

\[
\vec{R}_{d_2} = [-l_1 \dot{\theta}_1 s\theta_1 - \dot{u}_1 Ec\theta_1 - l_1 \dot{\theta}_1 c\theta_1 - x_2(\dot{\theta}_1 + \dot{\theta}_2)s(\theta_1 + \theta_2)
\]

\[
- \dot{u}_2 s(\theta_1 + \theta_2) - u_2(\dot{\theta}_1 + \dot{\theta}_2)c(\theta_1 + \theta_2)]\vec{u}_x + [l_1 \dot{\theta}_1 c\theta_1 + \dot{u}_1 Ec\theta_1 - u_1 \dot{\theta}_1 s\theta_1 + x_2(\dot{\theta}_1 + \dot{\theta}_2)c(\theta_1 + \theta_2) + \dot{u}_2 c(\theta_1 + \theta_2) - u_2(\dot{\theta}_1 + \dot{\theta}_2)
\]

\[
s(\theta_1 + \theta_2)]\vec{u}_y
\]

(2.8)
where the dot means the derivative with respect to time.

For any mass \( m_j \) concentrated at joint 2 the velocity will be the same as for the end of beam 1 and for any payload, the velocity will be the one at the end of beam 2.

2.3 Kinetic Energy

The kinetic energy of beams 1 and 2 can be expressed as

\[
T_b = T_1 + T_2 = 1/2 \int_{m_1} \dot{\vec{R}}_{d1} \cdot \dot{\vec{R}}_{d1} \, dm + 1/2 \int_{m_2} \dot{\vec{R}}_{d2} \cdot \dot{\vec{R}}_{d2} \, dm \quad (2.9)
\]

where \( dm \) is the element of mass at point \( P_i (i = 1,2) \) and \( m_1 \) and \( m_2 \) are the masses of beams 1 and 2 respectively.

If now (2.7) and (2.8) are substituted into (2.9) the result is:

\[
T_b = 1/2 \hat{\theta}_1^2 \int_{m_1} x_1^2 \, dm + 1/2 \int_{m_1} u_1^2 \, dm + \hat{\theta}_1 \int_{m_1} \dot{u}_1 x_1 \, dm +
\]

\[
1/2 \hat{\theta}_1^2 \int_{m_1} u_1^2 \, dm + 1/2 m_2 l_1 \hat{\theta}_1^2 + 1/2 m_2 u_{1E}^2 + 1/2 m_2 u_{1E}^2 \hat{\theta}_1^2 + m_2 l_1 \hat{\theta}_1 \dot{u}_{1E}
\]

\[
+ 1/2 (\hat{\theta}_1 + \hat{\theta}_2)^2 \int_{m_2} x_2^2 \, dm + 1/2 \int_{m_2} \dot{u}_2^2 \, dm + 1/2 (\hat{\theta}_1 + \hat{\theta}_2)^2 \int_{m_2} u_2^2 \, dm
\]
+ (\dot{\theta}_1 + \dot{\theta}_2) \int_{m_2} x_2 \dot{u}_2 \, dm + \lambda_1 \dot{\theta}_1 (\dot{\theta}_1 + \dot{\theta}_2) c \dot{\theta}_2 \int_{m_2} x_2 \, dm + \\
\lambda_1 \dot{\theta}_1 \dot{c} \dot{\theta}_2 \int_{m_2} u_2 \, dm + \dot{u}_1 \dot{\theta}_1 (\dot{\theta}_1 + \dot{\theta}_2) c \dot{\theta}_2 \int_{m_2} \dot{u}_2 \, dm + \\
\dot{u}_1 \dot{\theta}_1 (\dot{\theta}_1 + \dot{\theta}_2) s (-\dot{\theta}_2) \int_{m_2} u_2 \, dm + u_1 \dot{\theta}_1 (\dot{\theta}_1 + \dot{\theta}_2) s \dot{\theta}_2 \int_{m_2} x_2 \, dm + \\
\lambda_1 \dot{\theta}_1 (\dot{\theta}_1 + \dot{\theta}_2) s (-\dot{\theta}_2) \int_{m_2} u_2 \, dm + u_1 \dot{\theta}_1 (\dot{\theta}_1 + \dot{\theta}_2) c \dot{\theta}_2 \int_{m_2} u_2 \, dm + \\
u_1 \dot{\theta}_1 s \dot{\theta}_2 \int_{m_2} \dot{u}_2 \, dm \\
(2.10)

The same procedure can be applied to a mass concentrated at joint 2 and to a payload with moment of inertia \( J_{xp} \) with respect to an axis normal to the plane of motion and through the center of gravity. In fact, for the mass at joint 2 expression (2.7) can be modified to

\[ \ddot{R}_j = [-\dot{\theta}_1 l_1 s \theta_1 - \dot{u}_1 E s \theta_1 - \dot{\theta}_1 u_1 E c \theta_1] \ddot{u}_x + [\dot{\theta}_1 l_1 c \theta_1 + \dot{u}_1 E c \theta_1 \\
- u_1 \dot{\theta}_1 s \theta_1] \ddot{u}_y \]

(2.11)
and from expression (2.8)

\[
\ddot{R}_p = [-l_1\dot{\theta}_1 s_1 - \dot{u}_1 \dot{E} s_1 - u_1 \dot{E} c_1 - l_2 (\dot{\theta}_1 + \dot{\theta}_2) c (\theta_1 + \theta_2) - \dot{u}_2 \dot{E} s (\theta_1 + \theta_2)
- u_2 \dot{E} (\dot{\theta}_1 + \dot{\theta}_2) c (\theta_1 + \theta_2)] \ddot{x}_1 [l_1 \dot{\theta}_1 c_1 + \dot{u}_1 \dot{E} c_1 - u_1 \dot{E} c_1 s_1 + l_2 (\dot{\theta}_1 + \dot{\theta}_2)
- c (\theta_1 + \theta_2) + \dot{u}_2 \dot{E} c (\theta_1 + \theta_2) - \dot{u}_2 \dot{E} (\dot{\theta}_1 + \dot{\theta}_2) s (\theta_1 + \theta_2)] \ddot{y}
\] (2.12.1)

where

\(u_{2E}\) and \(\dot{u}_{2E}\) are flexible displacement and velocity of the end of beam 2. If the moment of inertia of the payload with respect to an axis through point \(O_2\) is defined by \(J_p\) and the angular displacement

\[
\begin{bmatrix}
\frac{\partial u_2}{\partial x_2} \\
\end{bmatrix}
\] \(x_2 = l_2 \) (2.12.2)

is taken into account, the total kinetic energy of the system can be finally expressed as:

\[
T = 1/2 \int_{m_1}^{R_{d1}} \ddot{R}_{d1} \cdot \dot{R}_{d1} dm + 1/2 \int_{m_2}^{R_{d2}} \ddot{R}_{d2} \cdot \dot{R}_{d2} dm + 1/2 m_j \ddot{R}_j \dot{R}_j +
\]
\[ + \frac{1}{2} m \mathbf{\ddot{R}} \cdot \mathbf{\ddot{R}}_p + \frac{1}{2} I_p \mathbf{\ddot{u}}_{2E}^2 \]  

(2.13)

2.4 Potential Energy

The potential energy of the system will be assumed as composed of the energy associated to the rigid motion plus the elastic potential energy of the links. Then, assuming \( Ox \) as the reference position, the first approximation of the total potential of the system is (assuming \( u_1 \) and \( u_2 \) sufficiently small)

\[
V = m_1 g \frac{l_1}{2} (1 - c\theta_1) + m_2 g l_1 (1 - c\theta_1) + m_2 g l_1 (1 - c\theta_1) +
\]

\[
\frac{l_2}{2} (1 - c(\theta_1 + \theta_2)) + m_2 g l_2 (1 - c\theta_1) + l_2 (1 - c(\theta_1 + \theta_2)) -
\]

\[1/2 \int_0^{l_1} EI_1 \left( \frac{\partial}{\partial x_1} \right)^2 u_1^2 \, dx - 1/2 \int_0^{l_2} EI_2 \left( \frac{\partial^2 u_2}{\partial x_2^2} \right) \, dx \]  

(2.14)

where

\( g \) is the component of gravity acceleration in the \( Ox \) direction, i.e.,
\[ \vec{G} = \begin{pmatrix} \vec{u} \end{pmatrix}^t \begin{pmatrix} g \\ 0 \end{pmatrix} \] (2.15)

\( EI_1, EI_2 \) are stiffnesses of links 1 and 2 respectively, assumed constant for the purpose of this model.

2.5 Equations of Motion

In order to write the equations of motion of the proposed system, it is possible to make use of the so called assume-modes method [M1]. Based upon this method, a solution of the flexible motions could be assumed as being composed of a linear combination of admissible functions multiplied by time-dependent generalized coordinates. Here, by admissible functions is meant any arbitrary function satisfying all the geometric or essential boundary conditions [C1]. Then, in case of the flexible displacements of beams 1 and 2, it is possible to assume

\[ u_1 = \sum_{i=1}^{n} \phi_{1i}(x_1)q_{1i}(t) \] (2.16.1)

\[ u_2 = \sum_{i=1}^{n} \phi_{2i}(x_2)q_{2i}(t) \] (2.16.2)

where the admissible functions \( \phi_{ji}(x) \) must satisfy the geometric boundary conditions with respect to the representation of the links in the reference frames \([0_1x_1y_1]\) and \([0_2x_2y_2]\).

It is clear that the system is now represented by a \((2n + 2)\) de-
degrees of freedom system where \([\theta_1(t), \theta_2(t)]\) and \([q_{1i}(t), q_{2i}(t), i=1,\ldots,n]\) are the generalized coordinates. Moreover, assuming that the amplitude of the higher modes of the flexible links is very small compared with the first one, the system can be truncated with \(n\) equal 2, resulting in a 6-degree of freedom problem.

The (2.16) assumes the form

\[
u_1 = \phi_{11}(x_1)q_{11}(t) + \phi_{12}(x_1)q_{12}(t)
\]

(2.17.1)

\[
u_2 = \phi_{21}(x_2)q_{12}(t) + \phi_{22}(x_2)q_{22}(t)
\]

(2.17.2)

If now, \(\phi_{ij}(i,j = 1,2)\) are assumed to be the eigenfunctions of a clamped-free beam, the geometric boundary conditions will be satisfied and because the orthogonality of these functions

\[
\int_0^1 \phi_r(x)\phi_s(x)dx = \begin{cases} 0 & (r = s) \\ 0 & (r \neq s) \end{cases}
\]

(2.18)

where

\[
\phi_r(x) = (cosh\lambda_rx - cos\lambda_rx) - \sigma_r(sinh\lambda_rx - sin\lambda_rx)
\]

(2.19)

as in reference \([B1]\), where \(r\) is the mode of vibrations and \(\lambda_r, \sigma_r\) are given by Table 2.1.
<table>

</tbody>
</table>

Table 2.1 Characteristic Values for Clamped-free Beam

Now the integrals in equations (2.10) and (2.14) can be evaluated.

\[
\int_{m_1} x_1^2 \, dm = J_0 
\]

\[
\int_{m_1} \dot{u}_1^2 \, dm = \int_{m_1} \phi_{11}^2 \dot{q}_{11}^2 \, dm + \int_{m_1} \phi_{12}^2 \dot{q}_{12}^2 \, dm = \dot{q}_{11}^2 \int_{m_1} \phi_{11}^2 \, dm + \dot{q}_{12}^2 \int_{m_1} \phi_{12}^2 \, dm = m_1 (\dot{q}_{11}^2 + \dot{q}_{12}^2) 
\]

\[
\int_{m_1} \dot{u}_1 x_1 \, dm = \int_{m_1} (\phi_{11} \dot{q}_{11} + \phi_{12} \dot{q}_{12}) x_1 \, dm = \dot{q}_{11} \int_{m_1} \phi_{11} x_1 \, dm + \dot{q}_{12} \int_{m_1} \phi_{12} x_1 \, dm = m_1 \cdot 1 \cdot \dot{q}_{11} + m_1 \cdot 2 \cdot \dot{q}_{12} 
\]

where
\[ \text{nw11} = \int_{m_1}^1 \phi_{11}x_1 dm = \int_0^l \nu_1 x \phi_{11}(x) dx \]  
(2.18.4)

\[ \text{nw12} = \int_{m_1}^1 \phi_{12}x_1 dm = \int_0^l \nu_1 x \phi_{12}(x) dx \]  
(2.18.5)

\[ \int_{m_1}^1 u_1^2 dm \text{ - neglected in the model} \]

\[ \int_{m_2}^1 x_2^2 dm = J_{01} \]  
(2.18.6)

\[ \int_{m_2}^1 \dot{x}_2^2 dm = m_2 (\dot{q}_{21}^2 + \dot{q}_{22}^2) \]  
(2.18.7)

\[ \int_{m_2}^1 u_2^2 dm \text{ - neglected in the model} \]

\[ \int_{m_2}^1 x_2 \dot{u}_2 dm = \text{nw21} \dot{q}_{21} + \text{nw22} \dot{q}_{22} \]  
(2.18.8)

where

\[ \text{nw21} = \int_{m_2}^1 \phi_{21}x_2 dm = \int_0^{l_2} \nu_2 x \phi_{21}(x) dx \]  
(2.18.9)

\[ \text{nw22} = \int_{m_2}^1 \phi_{22}x_2 dm = \int_0^{l_2} \nu_2 x \phi_{22}(x) dx \]  
(2.18.10)

\[ \int_{m_2}^1 x_2 dm = m_2 \frac{l_2}{2} \]  
(2.18.11)
\[ \int u_2 \, dm = \int \left( \phi_1 q_{21} + \phi_2 q_{22} \right) \, dm = q_{21} \int \phi_1 \, dm + q_{22} \int \phi_2 \, dm = \]

\[ n q_{21} \dot{q}_{21} + n q_{22} \dot{q}_{22} \quad (2.18.12) \]

where

\[ n q_{21} = \int \phi_{21} \, dm = \int_0^{l_2} u_2 \phi_{21}(x) \, dx \quad (2.18.13) \]

\[ n q_{22} = \int \phi_{22} \, dm = \int_0^{l_2} u_2 \phi_{22}(x) \, dx \quad (2.18.14) \]

\[ \int u_2 \, dm = \int \left( \phi_1 q_{21} + \phi_2 q_{22} \right) \, dm = n q_{21} q_{21} + n q_{22} q_{22} \quad (2.18.15) \]

For the potential energy, assuming EI constant for each beam and neglecting the effect of shear forces one can write

\[ \int_0^{l_1} E I_1 \left( \frac{\partial^2 u_1}{\partial x^2} \right)^2 \, dx = E I_1 \int_0^{l_1} \left( \phi_{11} q_{11} + \phi_{12} q_{12} \right)^2 \, dx = \]

\[ k w_{11} q_{11}^2 + k w_{12} q_{12}^2 \quad (2.19) \]

where the generalized springs are
\[ kw_{111} = EI_1 \int_0^1 (\phi_{11''} \phi_{11''}) dx \]  
(2.20.1)

\[ kw_{122} = EI_1 \int_0^1 (\phi_{12''} \phi_{12''}) dx \]  
(2.20.2)

\[ \frac{1}{2} E I_2 \int_0^1 \frac{a u_2^2}{\dot{x}_2^2} \, dx = kw_{211} q_{21}^2 + kw_{222} q_{22}^2 \]  
(2.21)

where

\[ kw_{211} = E I_2 \int_0^1 (\phi_{21''} \phi_{21''}) dx \]  
(2.22.1)

\[ kw_{222} = E I_2 \int_0^1 (\phi_{22''} \phi_{22''}) dx \]  
(2.22.2)

The total kinetic energy can then be written as

\[ T = \frac{1}{2}(J_0 + m_1 l_1^2) \dot{\theta}_2^2 + \frac{1}{2}m_1 (\dot{q}_{11}^2 + \dot{q}_{12}^2) + \frac{1}{2}m_3 (\theta_{11E} \dot{q}_{11}^2 + \theta_{12E} \dot{q}_{12}^2 + \phi_{11E} \dot{q}_{11} \dot{q}_{12}) + \dot{\theta}_2 [nw_{11} + m_1 l_1 \phi_{11E}] \dot{q}_{11} + \phi_{11E} \dot{q}_{11} + \phi_{12E} \dot{q}_{12} \]  

\[ \frac{1}{2}(m_2 + m_p) l_1 \dot{\theta}_2^2 + \frac{1}{2}(m_2 + m_p) (\phi_{11E} \dot{q}_{11} + \phi_{12E} \dot{q}_{12})^2 \]

\[ + \frac{1}{2}(m_2 + m_p) \dot{\theta}_2^2 (\phi_{11E} q_{11} + \phi_{12E} q_{12})^2 + (m_2 + m_p) l_1 \dot{\theta}_2 (\phi_{11E} \dot{q}_{11} + \phi_{12E} \dot{q}_{12}) \]

\[ + \frac{1}{2}(J_{01} + J_p) (\dot{\theta}_2 + \dot{\theta}_3)^2 + \frac{1}{2}m_2 (\dot{q}_{21}^2 + \dot{q}_{22}^2) + \]
\[
\frac{1}{2m_p}(\phi_{21E}q_{21} + \phi_{22E}q_{22})^2 + \cdot(\dot{\theta}_2 + \dot{\theta}_3) [\left(nw21 + m_pl_2\phi_{21E}\dot{q}_{21} + (nw22 + m_pl_2\phi_{21E}\dot{q}_{22}\right) + (m_2 + 2m_p) \frac{l_1l_2}{2} \dot{\theta}_2(\dot{\theta}_2 + \dot{\theta}_3)c\theta_3 + \\
l_1\dot{\theta}_2c\theta_3[(m_p\phi_{21E} + nq21)\dot{q}_{21} + (m_p\phi_{22E} + nq22)\dot{q}_{22}\right) + (\phi_{11E}q_{11} + \\
\phi_{12E}q_{12})(\dot{\theta}_2 + \dot{\theta}_3)(m_2 + 2m_p) \frac{l_2}{2} c\theta_3 + (\phi_{11E}q_{11} + \phi_{12E}q_{12})[(m_p\phi_{21E} + nq21)\dot{q}_{21} + (m_p\phi_{22E} + nq22)\dot{q}_{22}\right]c\theta_3 - (\phi_{11E}q_{11} + \phi_{12E}q_{12}) \\
(\dot{\theta}_2 + \dot{\theta}_3)[(m_p\phi_{21E} + nq21)q_{21} + (m_p\phi_{22E} + nq22)q_{22}])s\theta_3 + \\
(m_2 + 2m_p)(\phi_{11E}q_{11} + \phi_{12E}q_{12})\dot{\theta}_2(\dot{\theta}_2 + \dot{\theta}_3)s\theta_3 \frac{l_2}{2} + (\phi_{11E}q_{11} + \\
\phi_{12E}q_{12})\dot{\theta}_2[m_p\phi_{21E} + nq21)\dot{q}_{21} + (m_p\phi_{22E} + nq22)\dot{q}_{22}\right]s\theta_3 - \\
l_1\dot{\theta}_2(\dot{\theta}_2 + \dot{\theta}_3)[(m_p\phi_{21E} + nq21)q_{21} + (m_p\phi_{22E} + nq22)q_{22}])s\theta_3 + \\
(\phi_{11E}q_{11} + \phi_{12E}q_{12})\dot{\theta}_2(\dot{\theta}_2 + \dot{\theta}_3)[(m_p\phi_{21E} + nq21)q_{21} + (m_p\phi_{22E} + \\
nq22)q_{22}\right]c\theta_3 + \frac{1}{2m_p}(\phi_{21E}q_{21} + \phi_{22E}q_{22})^2 \\
(2.23)
\]

For the potential energy

\[
V = \left((m_1 + 2m_2 + 2m_p)\frac{l_1}{2} \right) (1 - c\theta_1) + (m_2 + 2m_p)\frac{l_2}{2}.
\]
\[ \begin{align*}
[1 - c(q_1 + q_2)]g + kw_{111} q_{11}^2 + kw_{122} q_{12}^2 + kw_{211} q_{21}^2 + \\
kw_{222} q_{22}^2 + k
\end{align*} \quad (2.24) \]

where:

- \( k \) is the reference potential energy for the flexible components
- \( \phi_{11E}, \phi_{12E} \) are end deflections of beam 1
- \( \phi_{21E}, \phi_{22E} \) are end deflections of beam 2
- \( \phi_{21E}^{'}, \phi_{22E}^{'} \) are the angles at end of beam 2
- \( g \) is the acceleration of gravity in \( X \) direction

If now \( \theta_1, \theta_2, q_{11}, q_{12}, q_{21}, q_{22} \) are assumed to be a set of generalized coordinates and \( \tau_1 \) and \( \tau_2 \) are nonconservative torques acting at the joints of the system, it is possible to write the equations of motion using Lagrange's equations for a nonconservative system. These equations have the form

\[ \frac{d}{dt} \left( \frac{\partial T}{\partial q_r} \right) - \frac{\partial T}{\partial q_r} + \frac{\partial V}{\partial q_r} = Q_r \quad r = 1, 2, \ldots, 6 \quad (2.25) \]

where \( Q_r \) are time-dependent nonconservative generalized forces (or torques). In this particular case, the torques \( \tau_1 \) and \( \tau_2 \) are going to realize work only for variations of \( \theta_1 \) and \( \theta_2 \). Then, if a variation \( \delta\theta_1 \) occurs at joint 1, with all other variables kept constant, the virtual work done is:
\[ \delta W = \tau_1 \delta_1 \] \hspace{1cm} (2.26)

and

\[ Q_1 = \frac{\delta W}{\delta \theta_1} = \tau_1 \] \hspace{1cm} (2.27)

Similarly

\[ Q_2 = \tau_2 \] \hspace{1cm} (2.28)

Also, from the definition of the angle \( \theta_2 \) given at the beginning of this chapter it is possible to show that the remaining generalized forces are equal to zero.

Then, the equations of motion become

\[ \dot{M}_{42} \ddot{\theta}_1 + \dot{M}_{12} \ddot{\theta}_2 + \dot{M}_{13} \ddot{q}_{11} + M_{14} \ddot{q}_{12} + \dot{M}_{15} \ddot{q}_{21} + M_{16} \ddot{q}_{22} = \]

\[ - \dot{M}_{B1} - F_1 + \tau_1 \] \hspace{1cm} (2.29.1)

\[ \dot{M}_{21} \ddot{\theta}_1 + \dot{M}_{22} \ddot{\theta}_2 + \dot{M}_{23} \ddot{q}_{11} + M_{24} \ddot{q}_{12} + M_{25} \ddot{q}_{21} + M_{26} \ddot{q}_{22} = \]

\[ - M_{B2} - F_2 + \tau_2 \] \hspace{1cm} (2.29.2)

\[F_5 = -mp21 l_1\dot{\theta}_1\dot{\theta}_2 s\theta_2 + 2(\phi_{1E}q_{11} + \phi_{1E}q_{12})mp21\dot{\theta}_1 s\theta_2 + l_1\dot{\theta}_1\]

\[(\dot{\theta}_1 + \dot{\theta}_2)mp21s\theta_2 - (\phi_{1E}q_{11} + \phi_{1E}q_{12})\dot{\theta}_1^2 mp21 c\theta_2 \quad (2.31.5)\]

\[F_6 = -mp22 l_1\dot{\theta}_1\dot{\theta}_2 s\theta_2 + 2(\phi_{1E}q_{11} + \phi_{1E}q_{12})mp22\dot{\theta}_1 s\theta_2 + l_1\dot{\theta}_1\]

\[(\dot{\theta}_1 + \dot{\theta}_2)mp22 s\theta_2 - (\phi_{1E}q_{11} + \phi_{1E}q_{12})\dot{\theta}_1^2 mp22 c\theta_2 \quad (2.31.6)\]

where

\[mp21 = mp \phi_{21E} + mq21 \quad (2.32.1)\]
\[ mp_{22} = mp_{22E} + nq_{22} \]  \hspace{1cm} (2.32.2)

Equations (2.29) can be written in matrix form

\[ M_1 (t) \ddot{\xi} = K_1 \xi + F_1 + C u \]  \hspace{1cm} (2.33)

where

\[ M_1(t) = [M_{1ij}] \quad i,j = 1, \ldots, 6 \]  \hspace{1cm} (2.34.1)

\[ K_1 = \begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & -kw_{111} & 0 & 0 & 0 \\
0 & 0 & 0 & -kw_{122} & 0 & 0 \\
0 & 0 & 0 & 0 & -kw_{211} & 0 \\
0 & 0 & 0 & 0 & 0 & -kw_{222}
\end{bmatrix} \]  \hspace{1cm} (2.34.2)

\[ F_1 = \begin{bmatrix}
+F_1 - MB_{11} \\
+F_2 - MB_{12} \\
-F_3 \\
-F_4 \\
-F_5 \\
-F_6
\end{bmatrix} \]  \hspace{1cm} (2.34.3)
\[ \mathbf{c} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{bmatrix} \]  

\[ \mathbf{u} = \begin{bmatrix} \tau_1 \\ \tau_2 \end{bmatrix} \]  

(2.34.4)  

(2.34.5)  

\[ \mathbf{\ddot{x}} = \begin{bmatrix} \ddot{\theta}_1 \\ \ddot{\theta}_2 \\ \dddot{q}_{11} \\ \dddot{q}_{12} \\ \dddot{q}_{21} \\ \dddot{q}_{22} \end{bmatrix} \]  

(2.34.6)  

\[ \mathbf{\ddot{x}} = \begin{bmatrix} \theta_1 \\ \theta_2 \\ q_{11} \\ q_{12} \\ q_{21} \\ q_{22} \end{bmatrix} \]  

(2.34.7)
A new set of variables can now be defined in order to write the equations of motion (2.33) in state space form.

In fact, if
\[
\begin{align*}
\zeta_1 &= \theta_1 \quad (2.35.1) \\
\zeta_2 &= \theta_2 \quad (2.35.2) \\
\zeta_3 &= q_{11} \quad (2.35.3) \\
\zeta_4 &= q_{12} \quad (2.35.4) \\
\zeta_5 &= q_{21} \quad (2.35.5) \\
\zeta_6 &= q_{22} \quad (2.35.6)
\end{align*}
\]
equation (2.33) will be
\[
\dot{\zeta} = A' \zeta + F' + C'u \quad (2.36)
\]
where

\[
\dot{\zeta} = [\dot{\zeta}_i] \quad (2.37.1)
\]
\[
\zeta = [\zeta_i] \\
i = 1, \ldots, 6 \quad (2.37.2)
\]
\[
A' = \begin{bmatrix}
0 & \vdots & 1 \\
\vdots & \ddots & \vdots \\
M_1^{-1}K_1 & \cdots & 0
\end{bmatrix} \quad (2.37.3)
\]
\[
F' = \begin{bmatrix}
0 \\
\vdots \\
M_1^{-1}F
\end{bmatrix} \quad (2.37.4)
\]
\[
C' = \begin{bmatrix}
0 \\
\vdots \\
M_1^{-1}B
\end{bmatrix} \quad (2.37.5)
\]
where $\dot{x}$, $x$ and $F'$ are (12x1) vectors, $A'$ is (12x12) and $C'$ is (12x2) matrix.

2.6 Linearized Equations

Equation (2.36) is used to study the motions of the proposed system under some designed control component $u$. For the purpose of design a linearized form of (2.36) is obtained. In doing so, all sines and cosines are first replaced by their series representation and then all terms of second- or higher degree in $x_i$, $i = 1, \ldots, 6$ are dropped from the equations. The resulting linearized system of equations can then be written as

$$\dot{x} = A x + B u$$  \hspace{1cm} (2.38)

where

$$A = \begin{bmatrix} 0 & \vdots & I \\ \vdots & \ddots & \vdots \\ M^{-1}k & \vdots & 0 \end{bmatrix}$$ \hspace{1cm} (2.39.1)

$$B = \begin{bmatrix} 0 \\ \vdots \\ M^{-1}b \end{bmatrix}$$ \hspace{1cm} (2.39.2)

and

$$M = [M_{ij}] \quad i, j = 1, \ldots, 6$$ \hspace{1cm} (2.39.3)
\[
K = \begin{bmatrix}
-M_{B111} & -M_{B112} & 0 & 0 & 0 & 0 \\
-M_{B121} & -M_{B122} & 0 & 0 & 0 & 0 \\
0 & 0 & -k_w111 & 0 & 0 & 0 \\
0 & 0 & 0 & -k_w122 & 0 & 0 \\
0 & 0 & 0 & 0 & -k_w211 & 0 \\
0 & 0 & 0 & 0 & 0 & -k_w222
\end{bmatrix}
\] (2.39.4)

where now

\[
M_{11} = (J_0 + m_j l_1^2) + (m_2 + m_p) l_1 l_2 + (J_{01} + J_p) + (m_2 + 2m_p) l_1 l_2 c \bar{\theta}_2
\] (2.40.1)

\[
M_{12} = (J_{01} + J_p) + (m_2 + 2m_p) \frac{l_1 l_2}{2} c \bar{\theta}_2
\] (2.40.2)

\[

\[ M_{34} = (m_2 + m_p + m_j)\phi_{11E} \phi_{12E} \quad (2.40.16) \]

\[ M_{35} = \phi_{11E}mp_{21} c\bar{e}_2 \quad (2.40.17) \]

\[ M_{36} = \phi_{11E}mp_{22} c\bar{o}_2 \quad (2.40.18) \]

\[ M_{41} = M_{14} \quad (2.40.19) \]

\[ M_{42} = M_{24} \quad (2.40.20) \]
\[ M_{43} = M_{34} \] (2.40.21)

\[ M_{44} = m_1 + \left( m_2 + m_j + m_p \right)^2 \phi_{12E} \] (2.40.22)

\[ M_{45} = \phi_{12E} m_p 21 c \bar{c} \] (2.40.23)

\[ M_{46} = \phi_{12E} m_p 22 c \bar{c} \] (2.40.24)

\[ M_{51} = M_{15} \] (2.40.25)

\[ M_{52} = M_{25} \] (2.40.26)

\[ M_{53} = M_{35} \] (2.40.27)

\[ M_{54} = M_{45} \] (2.40.28)

\[ M_{55} = m_2 + m_p \phi^{2}_{21E} + J_p \phi^{2}_{21E} \] (2.40.29)

\[ M_{56} = m_p \phi^{2}_{21E} \phi^{2}_{22E} + J_p \phi^{2}_{21E} \phi^{2}_{22E} \] (2.40.30)

\[ M_{61} = M_{16} \] (2.40.31)

\[ M_{62} = M_{26} \] (2.40.32)

\[ M_{63} = M_{36} \] (2.40.33)
\[ M_{64} = M_{46} \]  \hspace{1cm} (2.40.34)

\[ M_{65} = M_{56} \]  \hspace{1cm} (2.40.35)

\[ M_{66} = m_2 + m \phi_{22E}^2 + J \phi_{22E}^2 \]  \hspace{1cm} (2.40.36)

\[ MB_{111} = [(m_1 + 2m_j + 2m_2 + 2m_p) \frac{l_1}{2} \bar{c} \bar{\theta}_1 + (n_2 + 2m_p) \frac{l_2}{2} c(\bar{\theta}_1 + \bar{\theta}_2)]g \]  \hspace{1cm} (2.40.37)

\[ MB_{112} = [(m_2 + 2m_p) \frac{l_2}{2} g \bar{c}(\bar{\theta}_1 + \bar{\theta}_2)] \]  \hspace{1cm} (2.40.38)

\[ MB_{121} = [(m_2 + 2m_p) \frac{l_2}{2} g c(\bar{\theta}_1 + \bar{\theta}_2)] \]  \hspace{1cm} (2.40.39)

\[ MB_{122} = [(m_2 + 2m_p) \frac{l_2}{2} g c(\bar{\theta}_1 + \bar{\theta}_2)] \]  \hspace{1cm} (2.40.40)

and

\[ x_1 = \theta_1 - \bar{\theta}_1 \]  \hspace{1cm} (2.41.1)

\[ x_2 = \theta_2 - \bar{\theta}_2 \]  \hspace{1cm} (2.41.2)

\[ x_3 = q_{11} \]  \hspace{1cm} (2.41.3)

\[ x_4 = q_{12} \]  \hspace{1cm} (2.41.4)
\[ x_5 = q_{21} \]  \hspace{1cm} (2.41.5)

\[ x_6 = q_{22} \]  \hspace{1cm} (2.41.6)

with \( \theta_1 \) and \( \theta_2 \) being constant angles at some instant \( t \).

2.7 Experimental Verification

To know how well the model represents a real system an experiment was designed and built. It consisted of two carbon steel beams pinned together by a joint that allows motion only in the plane of the beams. One of the ends was connected to a torque motor for excitation and at the other extreme a payload was clamped as indicated in Figure 2.4. The joint was represented in the model by a lumped mass at the end of the first beam. The experiment was performed in the vertical plane in order to have the effects of the gravitational field. The frequency spectrum shown in Figure 2.5 was obtained by automatic frequency sweeping and measurement of the acceleration of the end point via an accelerometer mounted on the payload. As the model only takes into account two nodes for each beam, the overall system presents two rigid and four flexible natural frequencies. Table 2.2 summarizes the flexible resonant frequencies and the error relative to the experiment. As one can verify, the results are quite good if one takes into account all the possible measurement errors that might have been introduced by the automatic sweeping without allowing the system to reach the steady state. Another source of errors could well be introduced by the value of moment of inertia of the torque
Units: slug-ft-sec (kg-m-sec)

Torque Motor Rotor Inertia = 3.98 \times 10^{-4} \text{ ft-lbf-sec}^2 \\
(5.75 \times 10^{-4} \text{ nt-m-sec}^2)

Beams: diameter = 0.25 \text{ in (0.00635 m)}
material: carbon-steel

Joint material: Aluminum
mass = 1.23 \times 10^{-3} \text{ slugs (0.0179 kg)}

Payload mass = 4.875 \times 10^{-3} \text{ slugs (0.0711 kg)}
J_{cg} = 0.395 \times 10^{-4} \text{ slug-ft}^2 (0.669 \times 10^{-4} \text{ kg-m}^2)

Figure 2.4 - Experimental Verification - System Parameters
motor, which was obtained from a motor catalogue. As has been observed by W.J. Book [B2], a reduction of 30% in this value would lower the first three natural frequencies about 3.7%.

Another comparison of results was performed between the proposed model and the transfer-matrix procedure used in [B2]. For this purpose the chosen system was the correspondent model of a 53.4 ft. long manipulator. The dimensions are summarized in Figure 2.6 and the results in Table 2.3. In this case no gravity was taken into account and Table 2.3 presents the first four flexible natural frequencies.

From the results presented in these two comparisons, one might assume that the model gives a good representation of the proposed physical system with probably loss of significance only in the highest frequency due to truncation error. This kind of error was also observed when the proposed modeling procedure was applied to a single pinned-free beam. Table 2.4 presents some results comparing the proposed model applied to a single pinned-free beam in two situations: forced by the same torque motor and analytical values with dimensions shown in Figure 2.7, both cases assuming truncation at the second flexible mode.

2.8 Numerical Evaluations

As the number of modes introduced in the model increases, the system becomes more and more numerically stiff [L1]. This fact is reflected in the numerical calculations of the eigenvalues of the mathematical model. The previous results in this work were obtained by using a mini-computer Interdata Model 70, with 40K 16 bit words of core storage avail-
Units: slug-ft-sec (kg-m-sec)

Beams:
- External diameter = 0.75 ft (0.228 m)
- Internal diameter = 0.734 ft (0.223 m)
- Mass = 5.278 slugs (77.021 kg)

Joint
- Lumped mass = 1 slug (14.592 kg)

Payload
- Mass = 15.54 slugs (226.76 kg)
- $J_{c.g.} = 12.62$ slug-ft$^2$ (21.37 kg-m$^2$)
- Diameter = 1.0 ft (0.304 m)

Table 2.4 Analytical and Experimental Results from a Single Pinned-Free Beam
able at M.I.T. Joint Civil-Mechanical Engineering Computer Facility.
The general programs are listed in Appendix A. As the storage capacity
of the computer used was small compared with the size of the program,
the operations were performed utilizing disk storage.
3.1 Introduction

This chapter gives a general description of the techniques that were applied to the analysis of controlling flexible manipulators. These techniques, with one exception, were applied to the models presented in Chapter IV and the results are discussed in the next chapter. In order to introduce these control procedures one can start with equation (2.36) which represents the nonlinear model of the physical system

\[ \tau = A' \tau + F' + C' u \]  
(2.36)

The objective is to find a control law \( u(\tau, \dot{\tau}, t) \) such that the system response follows the desired specifications. This task is complicated by the presence of the nonlinear terms in the system representation.

Even in the case for which the control law can be exactly specified, it would in principle be useful only in very specific cases. To avoid this type of design of the control one can always design the compensation for the linearized model and verify how good the approach is when applied to the nonlinear system.

From the linearized equations of motion

\[ \dot{x} = A x + B u \]  
(2.38)
the structure of a linear regulator can be represented as in the block diagram of Figure 3.1

\[ \dot{x}_d \xrightarrow{\sum} K \xrightarrow{u} B \xrightarrow{+} \dot{x} \xrightarrow{1/s} A \]

**Figure 3.1** Block Diagram of the Compensated System.

where the control has been replaced by the linear equation

\[ u = K \dot{x} \]  \hspace{1cm} (3.1)

and \( x_d \) is the desired trajectory.

The purpose of this chapter is to present several techniques that were used to compute the set of gains \( K \) for different feedback alternatives.

3.2 Modal Analysis

It is well known that in the case of linear time invariant systems described by state equations of the form

\[ \dot{x} = A \dot{x} + B u \]  \hspace{1cm} (3.2)
where $A$ and $B$ are $(n \times n)$ and $(n \times r)$ matrices respectively, a model representation can be obtained by using a nonsingular transformation of state $[C3], [S1]$.

$$X = UZ \quad (3.3)$$

In the case of distinct eigenvalues of matrix $A$, matrix $U$ is the modal matrix of $A$ and its columns are the eigenvectors of $A$ $[G1] [C3]$. Then equation (3.1) becomes

$$\dot{Z} = \Delta Z + P^T u \quad (3.4.1)$$

where $\Delta$ is the diagonal matrix of the eigenvalues of $A$

$$\Delta = \begin{bmatrix}
\lambda_1 & & \\
& \lambda_2 & \\
& & \ddots \\
& & & \lambda_n
\end{bmatrix} \quad (3.4.2)$$

and

$$P^T = V^{-1}B = VTB \quad (3.4.3)$$

is the mode controllability matrix with

$$UV^T = I \quad (3.4.4)$$

where $I$ is the identity matrix.
It is clear from equations (3.4) that the transformation (3.3) uncouples the n-th order system into n uncoupled subsystems. Also it is evident from equations (3.4) that the ith mode of the uncoupled system is controllable by the jth control input if and only if

$$p_{ij} = v_i^T b_j \neq 0$$  \hspace{1cm} (3.5)

The controllability of the system is immediately verified by examining the components of the mode controllability matrix $P_i^T$.

Equations (3.3) represent an uncoupled system giving rise to one important question: is it possible to find a control law $u$ such that the eigenvalues can be specified a priori? The answer to this question was initially given by Rosenbrock [R1] and his presentation of modal control. Several extensions and improvements have been made since then [E1], [P1], [P2] and a very useful algorithm was presented in the work of Simon and Mitter [S1], [S2] for the case of distinct eigenvalues. A more recent work by Gould, Murphy and Berkman [G3] extends this algorithm for repeated eigenvalues. The constraints in the number of inputs in the present work make the Simon-Mitter algorithm the most suitable for applications. For this reason a brief presentation of this method will follow in a simplified way as it was applied. A rigorous and general formulation can be found in reference [S2].

3.3 Simon-Mitter Algorithm (SMA)

This algorithm is capable of shifting all the eigenvalues to desired
location with only one application. However, this procedure may cause numerical difficulties in the solution of a large number of ill-conditioned equations. On the other hand, the shifting technique is recursive, that is, a small number of poles can be shifted in each application of the algorithm and this procedure may be applied as many times as is necessary. If a number $p$ of poles is to be shifted the solution involves an inversion of a $(p \times p)$ matrix. For this reason a recursive design shifting two poles each time was used, which means that the procedure would involve a small amount of computer core for each change of poles. When two poles are moved, the gains to form the control law $u$ are such that two poles go to a new specified position while all the others remain fixed. If a new pair of poles is modified, the gains are all added to the old ones in order to maintain the former shifting of poles. This procedure has a disadvantage with respect to numerical errors accumulation but it is useful when few poles have to be shifted.

Again, the only restriction is that the system has no repeated poles.

In order to illustrate the two pole shift procedure one can recall the canonical form (3.4.1)

$$\dot{Z} = A Z + P^T u$$  \hspace{1cm} (3.4.1)

The question is to find a linear state variable feedback law

$$u = G Z = K x \quad (K = G \hat{V}^T)$$  \hspace{1cm} (3.6)
which moves the two selected poles to specified location while the other poles remain constant. If one chooses to change the poles \( \lambda_1 \) and \( \lambda_2 \) to \( \gamma_1 \) and \( \gamma_2 \) and assume that the system has \( r \) inputs the feedback law becomes

\[
 u = g_1 Z_1 + g_2 Z_2 = \begin{bmatrix} g_{11} \\ g_{21} \\ \vdots \\ g_{r1} \end{bmatrix} v_1^T x + \begin{bmatrix} g_{12} \\ g_{22} \\ \vdots \\ g_{r2} \end{bmatrix} v_2^T x \tag{3.7}
\]

Substitution of (3.6) into (3.4.1) yields the new system

\[
 \dot{z} = \Delta \dot{z} \tag{3.8.1}
\]

where

\[
 \Delta = \Delta + P^T G \tag{3.8.2}
\]

\[
 \Delta = \begin{bmatrix}
 \lambda_1 + \delta_{11} & \delta'_{12} \\
 \delta'_{21} & \lambda_2 + \delta'_{22} \\
 \delta'_{31} & \delta'_{32} & \lambda_3 \\
 \vdots & \vdots & \ddots & \ddots \\
 \delta'_{n1} & \delta'_{n2} & \cdots & \cdots & \lambda_n \\
 \end{bmatrix}
\tag{3.9.1}
\]
where
\[ \delta^i_{ik} = p^T_k g_k \quad \text{for } i = 1, \ldots, n \quad k = 1, \ldots, r \] (3.9.2)

To determine the new eigenvalues it is sufficient [S1] to examine the eigenvalues of

\[ \bar{\Delta}_{11} = \begin{bmatrix}
\lambda_1 + \delta^i_{11} & \delta^i_{12} \\
\delta^i_{21} & \lambda_2 + \delta^i_{22}
\end{bmatrix} \] (3.10.1)

In fact, from the mode decomposition property (Appendix B)

\[ \det(sI - \bar{\Delta}) = \prod_{j=3}^{n} (s - \lambda_j) \cdot \det(sI - \bar{\Delta}_{11}) \] (3.10.2)

If now the new pair of eigenvalues is \( \gamma_1 \) and \( \gamma_2 \) it is sufficient to equate the coefficients of like powers of the identity

\[ (s - \gamma_1)(s - \gamma_2) = \det(sI - \bar{\Delta}_{11}) \] (3.11)

and consequently find the conditions that must be satisfied by \( g_1 \) and \( g_2 \). However, \( g_1 \) and \( g_2 \) are vectors whose dimension depends upon the number of inputs to the system. If the system has a single input it is clear that (3.10) will give a unique solution for the control law \( u \). On the other hand, if \( r \neq 1 \) there exist an infinite number of components for \( g_1 \) and \( g_2 \) that satisfy (3.10). Several alternatives exist to produce a unique solu-
ution for the control. Among these techniques are those based on power requirements of the system, sensitivities, proportionality between control elements, etc. For the purpose of this application the criterion used is the fixed ratio of feedback gains, that is, the vectors $g_1$ and $g_2$ were replaced by $\eta_1 g_0$ and $\eta_2 g_0$ respectively. The vector $g_0$ is usually chosen on the sense of satisfying some desired condition. In particular, the selection of the elements of $g_0$ by the rule [S1]

$$g_{i0} = \text{sign}(p_{i1}) \quad i = 1, \ldots, r$$

(3.12)

maximizes the measure of controllability and hence requires the least absolute value of feedback gains. This rule was used throughout the applications. Since $g_0$ is specified the algorithm gives a unique solution for a shift of a pair of poles. This solution can be presented for two cases: pair of real poles and a complex conjugate pair. In particular, the numerical implementation becomes easier when these two cases are taken into account.

3.3.1 Real Pair of Poles $\lambda_1$ and $\lambda_2$ ($\lambda_1 \neq \lambda_2$)

In this case, (3.11) yields

$$\begin{bmatrix} \eta_1 \\ \eta_2 \end{bmatrix} = \begin{bmatrix} \alpha_{10} & \alpha_{20} \\ \lambda_2 \alpha_{10} & \lambda_1 \alpha_{20} \end{bmatrix}^{-1} \begin{bmatrix} \epsilon_1 \\ \epsilon_2 \end{bmatrix}$$

(3.13.1)

where
\( \epsilon_1 = \gamma_1 + \gamma_2 - \lambda_1 - \lambda_2 \)  \hspace{1cm} (3.13.2)

\( \epsilon_2 = \gamma_1 \gamma_2 - \lambda_1 \lambda_2 \)  \hspace{1cm} (3.13.3)

\[ a_{ko} = p_k^T g_0 \quad k = 1, \ldots, n \]  \hspace{1cm} (3.13.4)

and the control law

\[ u = g_0 \left[ n_1 v_1 + n_2 v_2 \right]^T x \]  \hspace{1cm} (3.13.5)

3.3.2 Complex Conjugated Poles

For this case, in order to assure that \( u \) is real let

\[ \lambda_1 = \lambda_1' + j \lambda_1'' \]  \hspace{1cm} (3.14.1)

\[ \lambda_2 = \lambda_1^* = \lambda_1' - j \lambda_1'' \]  \hspace{1cm} (3.14.2)

and from the mode controllability matrix let

\[ p_1 = p_1' + j p_1'' \]  \hspace{1cm} (3.14.3)

\[ p_2 = p_1^* = p_1' - j p_1'' \]  \hspace{1cm} (3.14.4)

\[ v_1 = v_1' + j v_1'' \]  \hspace{1cm} (3.14.5)
\[ v_2 = v_1^* = v_1' - jv_1" \]  

(3.14.6)

Then, the solution of

\[
\begin{bmatrix}
\eta' \\
\eta"
\end{bmatrix} = 
\begin{bmatrix}
P_1^T g_0 & -P_1^T g_0 \\
P_1^T g_0 & P_1^T g_0
\end{bmatrix}
^{-1}
\begin{bmatrix}
\varepsilon_{1/2} \\
(\varepsilon_2 - \lambda_1' \varepsilon_1) / 2 \lambda_1"
\end{bmatrix}
\]

(3.14.7)

leads to the control law

\[ u = 2g_0[\eta' v_1' - \eta" v_1"]^T x \]  

(3.15)

The transformation of a real pair of poles into a complex pair and vice versa can be easily obtained by successive numerical applications. Appendix A presents the computer program used for the applications of modal control using this algorithm in a recursive way.

3.4 General Rigid Gains - Cross Joint Feedback (GRG)

The preceding algorithm when applied to system (2.38) can move any pole to the desired position. However, the control law \( u \) used for this pole shifting will involve the measurements and/or estimation of all state variables associated with the physical system. Although the possibility of using measurements of all of the variables is not impossible, another technique was used in order to compare the results. Essentially,
this other procedure is to compute the gains for the control of a two link rigid manipulator and apply them to the flexible model. The control for the rigid system would use only position and velocity feedback gains involving the joint state variables. Several methods exist to compute this kind of gains but one particular procedure suggested by Professor D.E. Whitney [W1] seems appealing because of its similarity to a modal approach. A brief description of this method is presented below.

Consider a pure rigid two link system with no damping and no joint compliance represented by the equations

\[ \dot{\underline{\Omega}} = \underline{\tau} \]  \hspace{1cm} (3.16)

where \( \underline{J} \) is the (2x2) inertia matrix of the system, \( \underline{\tau} \) is the (2x1) vector of control torques and \( \underline{\Omega} \) is a vector with components \( \Omega_1 \) and \( \Omega_2 \), shoulder and elbow angles in the rigid system respectively. In terms of state variables (3.16) can be written

\[
\begin{bmatrix}
\dot{\Omega}_1 \\
\dot{\Omega}_2
\end{bmatrix} = \begin{bmatrix}
0 & I \\
0 & 0
\end{bmatrix} \begin{bmatrix}
\Omega_1 \\
\Omega_2
\end{bmatrix} + \begin{bmatrix}
0 \\
0
\end{bmatrix} \underline{\tau}
\]  \hspace{1cm} (3.17)

where \( I \) is the identity matrix.

The torques are obtained via a control law

\[ \underline{\tau} = \underline{B} \underline{u} \]  \hspace{1cm} (3.18)

with \( \underline{B} \) a (2x2) matrix and

\[ \underline{u} = k_T \underline{\Omega} + k_T D \dot{\underline{\Omega}} \]  \hspace{1cm} (3.19)
where $k_T$ is a $(2 \times 2)$ angular position feedback matrix and $k_{TD}$ is a $(2 \times 2)$ angular velocity feedback matrix. The elements of $k_T$ and $k_{TD}$ can be obtained for some desired specifications with respect to the position of the poles in the complex plane. The system (3.16) with (3.17) and (3.18) becomes

$$\begin{bmatrix}
\dot{\Omega} \\
\ddot{\Omega}
\end{bmatrix} = \begin{bmatrix}
0 & I \\
J^{-1}k_T & J^{-1}k_{TD}
\end{bmatrix} \begin{bmatrix}
\Omega \\
\dot{\Omega}
\end{bmatrix}$$

(3.20)

If now $k_T$ and $k_{TD}$ are chosen so that (*)

$$J^{-1}k_T = \begin{bmatrix}
-w_1^2 & 0 \\
0 & -w_2^2
\end{bmatrix}$$

(3.21.1)

$$J^{-1}k_{TD} = \begin{bmatrix}
-2\zeta_1 w_1 & 0 \\
0 & -2\zeta_2 w_2
\end{bmatrix}$$

(3.21.2)

it is clear that the system (3.16) will become a set of two uncoupled differential equations with natural frequencies $w_1$ and $w_2$ and damping ratios $\zeta_1$ and $\zeta_2$ respectively. This choice of $k_T$ and $k_{TD}$ is not unique but it is convenient because it allows one to place the poles by inspection. Then, this procedure enables one to specify the desired characteristic of the system and as a consequence find the corresponding angular position and velocity feedbacks.

Since for a real system the inertia matrix is always non-singular, (*) $w$ and $\omega$ are used interchangeably to represent angular frequency.
the only restriction to the technique is that the control matrix $B$ is non-singular. This fact makes impossible the application of this procedure to the flexible model itself but some variations of the control derived from a corresponding rigid model can be applied to the flexible system. Also it is important to notice that the matrices $K_T$ and $K_{TD}$ are not necessarily diagonal which means that the control can take into account feedback between the joints. Finally this procedure can be applied to a rigid arm with any number of joints. A trivial generalization allows the procedure to be applied to any controllable and observable lumped passive dynamic system although an observer may be needed.

3.5 Rigid Gains - No Cross Joint Feedback

This case is a particular way to find the $K_T$ and $K_{TD}$ matrices in the preceding method. As was mentioned before, the effect of cross joint feedback disappears when $K_T$ and $K_{TD}$ are chosen diagonal matrices. Using this procedure W.J. Book [B2] achieved interesting results for the design of control for flexible manipulators. This method was not applied in the present work except as a means of comparison of different control techniques.

3.6 Sensitivity Analysis

Another procedure used to find the components of the control law $u$ dealt with the sensitivities of the poles with respect to variations in the gains. If one assumes only angular position and velocity feedbacks, the number of control elements would be considerably reduced and by inspection the gains could be changed based on their corresponding sensi-
tivities.

Consider the system represented by

\[ \dot{x} = A x + B u \]  \hspace{1cm} (2.37)

and assume that

\[ u = K x \]  \hspace{1cm} (3.22)

where \( A \) is \((nxn)\) matrix, \( B \) is \((nxr)\) control matrix and \( K \) is \((rxn)\) gain matrix. For example, equation (2.38) could represent the linearized model of a flexible manipulator. The eigenvector \( u_j \) associated with the \( j \)th eigenvalue \( \lambda_j \) is defined by the equation

\[ A u_j = \lambda_j u_j \]  \hspace{1cm} (3.23)

If \( v_j \) is the corresponding element in the reciprocal basis, from the orthogonality of the modes

\[ v_j^T u_j = \delta_{ij} \begin{cases} \delta_{ij} = 0 & \text{for } i \neq j \\ \delta_{ij} = 1 & \text{for } i = j \end{cases} \]  \hspace{1cm} (3.24)

From (3.23) and (3.24)

\[ v_j^T A u_j = \lambda_j \]  \hspace{1cm} (3.25.1)
It is easy to verify that the only left hand side term involving the element \( a_{ik} \)

\[
... + v_{ji} a_{ik} u_{kj} + ... = \lambda_j
\]  

(3.25.2)

Then, from (3.24) and (3.25) the sensitivity of the eigenvalue \( \lambda_j \) with respect to variations in the element \( a_{ik} \) of the \( A \) matrix is given by [VI]

\[
\frac{\delta \lambda_j}{\delta a_{ik}} = v_{ji} u_{kj}
\]  

(3.26)

If now the control law (3.22) is taken into account, equation (2.38) reduces to

\[
\dot{x} = \bar{A} x
\]  

(3.27.1)

where

\[
\bar{A} = A + B K
\]  

(3.27.2)

with components

\[
\bar{a}_{ij} = a_{ij} + \sum_{k=1}^{r} b_{ik} g_{kj}
\]  

(3.27.3)
Now, the sensitivity of a pole $\lambda_\alpha$ with respect to gain $g_{kj}$ is

$$\frac{\partial \lambda_\alpha}{\partial g_{kj}} = \sum_{i=1}^{n} \sum_{k=1}^{r} \frac{\partial \lambda_\alpha}{\partial a_{ij}} \cdot \frac{\partial a_{ij}}{\partial g_{kj}} = \sum_{i=1}^{n} \frac{\partial \lambda_\alpha}{\partial a_{ij}} \left( \sum_{k=1}^{r} \frac{\partial a_{ij}}{\partial g_{kj}} \right) \quad (3.28)$$

But

$$\frac{\partial a_{ij}}{\partial g_{kj}} = b_{ik} \quad (3.29)$$

Then it follows from (3.28) and (3.29) that

$$\frac{\partial \lambda_\alpha}{\partial g_{kj}} = \sum_{i=1}^{n} \frac{\partial \lambda_\alpha}{\partial a_{ij}} b_{ik} \quad (3.30)$$

From (3.30) and (3.26) one can see that if the eigenvectors corresponding to a certain configuration are known, it is possible to analyze the effects of local pole variations for each component of the gain matrix. This procedure will be explained numerically in the next chapter.

3.7 Summary

This chapter presented a brief description of the control techniques used in this work. The next chapter presents the application of these techniques to some nondimensionalized examples and general results obtained.
CHAPTER IV

APPLICATIONS AND RESULTS

4.1 Introduction

The purpose of this chapter is to introduce the example systems used in the applications of the mathematical techniques and the general results obtained from the several control methods. Two examples have been chosen, both with circular ring cross sections. The first one (example 1) is a very long and flexible beam of two equal segments carrying a payload that might vary in size and weight. The overall dimensions are shown in Figure 4.1 and were obtained from reference [N1].

Beams:
- External diameter = 0.75 ft (0.228 m)
- Internal diameter = 0.734 ft (0.223 m)
- Material: Aluminum
- \( E = 10^7 \) psi (7.0x10^{10} Pa)

Figure 4.1 Example 1 Characteristics
The second example (example 2) is a more rigid system with fixed payload. The most important difference is that the beams have different radii and were chosen such that the stiffness EI for the first beam is approximately equal to six times the value for the second beam. The main geometric characteristics are presented in Figure 4.2 and were obtained from reference [R2].

Beam 1: external diameter = 3.74 in (0.095 m)
      internal diameter = 3.15 in (0.080 m)

Beam 2: external diameter = 2.36 in (0.060 m)
      internal diameter = 2.00 in (0.051 m)

Material: Aluminum  $E = 10^7$ psi $(7.0 \times 10^{10}$ Pa)

Joint lumped mass = 0.932 slugs (13.6 kg)

Assumed payload:

0.623 slugs (9.1 kg)  0.623 slugs (9.1 kg)

Figure 4.2 Example 2 Characteristics
With respect to all the applications of the described models, the motions were assumed to be in the plane of the beams, no structural damping was considered and gravity was neglected. However, the computer programs presented in Appendix A can accommodate damping and gravity.

4.2 Nondimensionalization

In order to have a better idea about the effect of the system parameters and also to obtain more general results, a system nondimensionalization was performed using the quantities given in Table 4.1.

<table>

</tr>
</tbody>
</table>

Table 4.1 Parameters for Nondimensionalization

where

\[ l = l₁ + l₂ \]  \hspace{1cm} (4.1.1)

\[ μ = \frac{μ₁l₁ + μ₂l₂}{l} \] \hspace{1cm} (4.1.2)

Two important quantities can be derived from Table 4.1

- time \[ T_d = \sqrt{\frac{μ₁l₃}{EI₁}} \] \hspace{1cm} (4.2.1)
It is important to observe that frequency \( w_d \) has no associated physical system but can be easily related to any system natural frequency. For example, if one considers a beam with stiffness \( EI_1 \), length \( l \) and density per unit length \( \nu \), the clamped-free natural frequency is given by

\[
w_c = 3.52 \sqrt{\frac{EI_1}{\nu l^3}}
\]  

(4.3)

Then it follows that the relationship between frequencies \( w_d \) and \( w_c \) is simply given by

\[
w_c = 3.52 w_d
\]  

(4.4)

Any results with respect to \( w_d \) can then be extended to compare with \( w_c \). If now one introduces:

- ratio of the radii of beam 1
  \[
k_{r1} = \frac{r_{i1}}{r_{e1}}
\]  

(4.5)

- ratio of the radii of beam 2
  \[
k_{r2} = \frac{r_{i2}}{r_{e2}}
\]  

(4.6)

it is possible to establish a constraint among the stiffness constant, the radius and the density of the beams. In fact, if one assumes the ratio of the radii for each beam and also the nondimensionalized stiffness constant of beam 2, the following relationships are useful for the
nondimensionalization of the remaining parameters.

In fact, if

$$\frac{EI_2}{EI_1} = \left(\frac{r_{e_2}}{r_{e_1}}\right)^4 \frac{(1-k_{r_2}^4)}{(1-k_{r_1}^4)}$$

then

$$\left(\frac{r_{e_2}}{r_{e_1}}\right)^2 = \sqrt{\frac{EI_2}{EI_2} \frac{(1-k_{r_1}^4)}{(1-k_{r_2}^4)}}$$

Also, from (4.1.1)

$$\mu = \frac{\mu_1 l_1 + \mu_2 l_2}{l} = \mu_1 \bar{l}_1 + \mu_2 \bar{l}_2$$

or

$$\bar{\mu}_1 \bar{l}_1 + \bar{\mu}_2 \bar{l}_2 = 1$$

On the other hand, for cylindrical beams

$$\mu = \rho \pi [\bar{l}_1 r_{e_1}^2 (1-k_{r_1}^2) + \bar{l}_2 r_{e_2}^2 (1-k_{r_2}^2)]$$

and

$$\frac{\bar{\mu}_1}{\bar{\mu}_2} = \frac{\rho \pi r_{e_1}^2 (1-k_{r_1}^2)}{\rho \pi [\bar{l}_1 r_{e_1}^2 (1-k_{r_1}^2) + \bar{l}_2 r_{e_2}^2 (1-k_{r_2}^2)]]}$$
or, using (4.7) into (4.10)

\[
\mu_1 = \frac{1}{\overline{l}_1 + \overline{l}_2 \sqrt{EI_2 \frac{(1 + k_{r1}^2)(1 - k_{r2}^2)}{(1 + k_{r2}^2)(1 - k_{r1}^2)}}}
\]

(4.11)

and from (4.8)

\[
\overline{\mu}_2 = 1 - \frac{\overline{\mu}_1 \overline{l}_1}{\overline{l}_2}
\]

(4.12)

Then, assuming the value of \(EI_2\), the ratio \(k_{r1}\) and \(k_{r2}\), the lengths \(\overline{l}_1\) and \(\overline{l}_2\) and one of the external radii, expressions (4.7), (4.11) and (4.12) define the other characteristics of the system.

Using \(EI_1\), \(\mu\) and \(l\) the nondimensionalized groups are shown in Table 4.2.

4.3 The Control Application and Arm Bandwidth Definitions

In order to apply the control techniques described in Chapter III it is helpful to know some details of the gain matrix $K$ that appears in equation (3.1). The model described in Chapter II was assumed to have two inputs, namely the torques $\tau_1$ and $\tau_2$ applied at shoulder and elbow joints, respectively. As the model is described by 12 state variables, $K$ is a $(2 \times 12)$ matrix. The general form of this matrix is

$$
K = \begin{bmatrix}
  k_{11} & k_{12} & k_{13} & k_{14} & k_{15} & k_{16} & k_{17} & k_{18} & k_{19} & k_{110} & k_{111} & k_{112} \\
  k_{21} & k_{22} & k_{23} & k_{24} & k_{25} & k_{26} & k_{27} & k_{28} & k_{29} & k_{210} & k_{211} & k_{212}
\end{bmatrix}
$$

(4.13)

where

$k_{11}, k_{12}, k_{21}, k_{22}$ are angular position feedback gains; $k_{13}, k_{14}, k_{15}, k_{16}, k_{17}, k_{23}, k_{24}, k_{25}, k_{26}, k_{27}$ are linear position feedback gains; $k_{17}, k_{18}, k_{27}, k_{28}$ are angular velocity feedback gains; $k_{19}, k_{110}, k_{111}, k_{112}, k_{29}, k_{210}, k_{211}, k_{212}$ are linear velocity feedback gains.

It is obvious that the linear feedbacks will necessarily require measurements and/or estimation of flexible displacements and velocities while the angular feedbacks are based essentially on the measurements of angles. This is an important fact in comparing the results from the application of general rigid gains design method and Simon-Mitter algorithm. Modal control will involve the set of 24 gains while in the
other case 8 at most are necessary. In the special case where no cross joint feedback is taken into account, only four gains are used [B2]. Due to the large number of gains, the analysis via a root locus for gains variations is impractical.

The remaining parts of this work will frequently mention arm bandwidth when comparisons or simulations are presented. There is a certain arbitrariness in defining the bandwidth of a manipulator arm. For this reason this work defines arm bandwidth as the maximum undamped frequency for which the two first dominant poles are as close as possible to 0.707 damping ratio. The following results are concerned with the arm bandwidth obtained by using the control techniques presented in the previous chapter.

4.4 General Rigid Gains Method Applications

For the implementation of this method one nondimensionalized example was chosen with the following parameters:

<table>
<thead>
<tr>
<th>$k_r 1 = k_r 2 = 0.9$</th>
<th>$\bar{J}_p = 0.0$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\bar{E}I_1 = 1.0$</td>
<td>$\bar{l}_p = 0.0$</td>
</tr>
<tr>
<td>$\bar{E}I_2 = 1.0$</td>
<td>$\bar{l}_1 = 0.5$</td>
</tr>
<tr>
<td>$\bar{\mu}_1 = 1.0$</td>
<td>$\bar{l}_2 = 0.5$</td>
</tr>
<tr>
<td>$\bar{\mu}_2 = 1.0$</td>
<td>$\bar{r}_{e1} = 0.05$</td>
</tr>
<tr>
<td>$\bar{m}_p = 0.0$</td>
<td>$\bar{r}_{e2} = 0.05$</td>
</tr>
<tr>
<td>$\bar{m}_j = 0.0$</td>
<td>$\theta_1 = 0^\circ$</td>
</tr>
<tr>
<td></td>
<td>$\theta_2 = 0^\circ$</td>
</tr>
</tbody>
</table>

Table 4.3 Nondimensionalized Parameters of Example 3
Similar tables for examples 1 and 2 can be found in Appendix C.

In order to obtain some results using this method one has to use an equivalent rigid model that in the case of present work is represented by a double pendulum with inputs at both pinned joints. It is evident that only angular position and velocity feedback gains will be present in such a model. If equations (3.2.1) are recalled, one will notice that to find the matrices $K_T$ and $K_{TD}$, it is necessary to specify four parameters of the desired system, namely, $w_1$, $w_2$, $\zeta_1$, $\zeta_2$. Once these values are specified, one can obtain $K_T$ and $K_{TD}$ such that the poles of the closed loop system will be exactly at the desired location. These gains can now replace the angular position and velocity feedbacks on the gain matrix (4.13), corresponding to the flexible case. In this way it is possible to analyze how effective the method is for several variations in the parameters. The following steps represent the application procedure:

a) choose the desired values of the first two dominant modes, that is, $w_1$, $w_2$, $\zeta_1$, $\zeta_2$;

b) using (3.21) applied to the rigid equivalent model obtain the gain matrices $K_T$, $K_{TD}$;

c) construct the gain matrix $K$ expression (4.13) using $K_T$ and $K_{TD}$;
d) examine the closed-loop poles of the flexible system.

The limiting range of this method will be determined by the deviation of the dominant poles of the flexible model from the desired specifications.

This sequence was applied to the example of Table 4.3 with the frequencies nondimensionalized by (4.2) and the assumption
\[ \bar{w}_1 = \bar{w}_2 = \bar{w} \quad (4.14a) \]
\[ \zeta_1 = \zeta_2 = \zeta \quad (4.14b) \]

where

\[ \bar{w} = \frac{w}{w_d} \]

It is important to mention that assumption (4.14) was used because it yields symmetric matrices \( K_T \) and \( K_{TD} \). This fact will make the control of the flexible model analogous to spring and dashpots actuating among the joints and consequently assuring stability for the system. Some results were obtained for \( w_1 \neq w_2 \) as can be seen in Figure 4.3. However to assure stability (4.14) assumption was used throughout the work with damping ratio \( \zeta = 0.7 \) as a constant parameter.

For this damping ratio \( \zeta \) the frequency \( \bar{w} \) was specified and gains \( K_T \) and \( K_{TD} \) were obtained via the rigid model; these gains when applied to the flexible model returned a pair of dominant poles which were plotted as a root-locus of the first two dominant flexible poles. The locus is shown in Figure 4.4 for damping ratios of 0.5, 0.7 and 0.8. A reasonable understanding of the results can be obtained by plotting both poles on the same graph. One can see that for \( \bar{w} = 1.0 \) the resulting behavior of the flexible system is essentially the same as the rigid one; the dominant poles are close together with damping ratio 0.7. As the value of \( \bar{w} \) is increased, the poles of the flexible system start separating and for \( \bar{w} \) over 3.0 there is a shift with respect to the distance to origin.
Figure 4.3 - Root locus of dominant poles - OGO Control for constant damping ratio $\xi = 0.7$ and $\omega_1 + \omega_2$
Figure 6.4a - Small root test of constant slope
GB Control varying $\gamma$

Figure 6.4b - Small root test of gradient slope
GB Control varying $\gamma$
and the dominant pole becomes the one that has a smaller damping ratio. On the other hand, if one recalls expression (4.4) it is easy to see that this relationship holds for the present example. Consequently

$$\bar{w} = \frac{w}{w_d} = \frac{1}{3.52} \cdot \frac{w}{w_c}$$  \hspace{1cm} (4.15)$$

is useful to compare the preceding explanation with respect to the natural frequency of a clamped-free beam associated with the system. Using (4.15) one might say that the method of general rigid gains yields very reasonable results for manipulator bandwidth up to the natural frequency of the clamped-free equivalent system. Faster response can be obtained only with a considerable reduction in the damping ratio of the dominant mode. For constant specified damping ratio of $\zeta = 0.7$

Figure 4.5 shows the dominant flexible poles for variations in $\bar{w}$. This plot presents a better view of the limitations obtained from the general rigid gains method.

4.5 Effect of Payload

In order to analyze the effect of the payload in the design of the control, a comparison was made between three different payloads for the example presented in Table 4.3. The payloads were assumed to be lumped masses at the end of the second beam with values indicated in Table 4.4
GRG Control

</tr>
</tbody>
</table>

Table 4.4 Lumped Payloads Assumed for Example 3

The natural frequency of the clamped-free equivalent system is $\omega_c = \alpha \sqrt{EI/\mu L^4}$ with $\alpha$ obtained using the method presented in reference [B1]. The results can be seen in Figure 4.6. As the payload is increased, the arm bandwidth is reduced as a consequence of the lower system natural frequencies. If one assumes the best design situation to be as close as possible to a damping ratio of 0.7 one sees that the general rigid gains method can still be applied with good results up to close to the clamped-free equivalent natural frequency. The situation would be considerably different if rotary inertia of the payload were considered.

4.6 Variations in System Geometry

In the preceding discussion only the case of equal cross section was verified from the point of view of control application. However, it would be useful to know how the system geometry has to be taken into account in order to improve the arm bandwidth. In order to implement this idea it is necessary to mention some important aspects. First, the system is going to be assumed, as in the previous cases, with two beams of equal length. Then, in order to keep a good reference for comparisons, the sum of the masses of the beams is assumed to be constant and the only variations must occur in the radii of the beams. In doing
$\bar{e}_p = 0.8 \quad \alpha = 1.63$
$\bar{e}_p = 1.0 \quad \alpha = 1.44$
$\bar{e}_p = 5.0 \quad \alpha = 0.75$

GRA Control
$\bar{e} = 0.707$
$\bar{e}_1 = \bar{e}_2$

Values of $\bar{e}$ for each case:
1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 8.0, 10.0

Figure 4.6 - Root test of contact planes - GRA Control
so let one assume

\[ m_1 + m_2 = m = \text{constant} \quad (4.16) \]

\[ l_1 + l_2 = l = \text{constant} \quad (4.17) \]

If \( \rho \) is the density of the material, equation (4.16) can be written

\[ \rho l_1 \frac{\pi}{4} d_{e1}^2 (1-k_{r1}^2) = \rho l_2 \frac{\pi}{4} d_{e2}^2 (1-k_{r2}^2) = m \quad (4.18) \]

or, using the nondimensionalization from Table 4.1, (4.18) can be reduced to

\[ \frac{\bar{l}_1 (1-k_{r1}^2)}{r_{e1}} + \left( \frac{r_{e2}}{r_{e1}} \right)^2 \frac{\bar{l}_2 (1-k_{r2}^2)}{l_1^3} = \frac{m}{\rho d_{e1}^2 \frac{\pi}{4} l_1^3} \quad (4.19) \]

If now one uses equation (4.7) there results

\[ \bar{d}_{e1}^2 = \left( \frac{m}{\rho \frac{\pi}{4} l_1^3} \right) \left( \frac{1}{\bar{l}_1 (1-k_{r1}^2) + \bar{l}_2 (1-k_{r2}^2)} \right) \frac{\sqrt{\frac{\bar{E} I_2}{l_1^3}} (1-k_{r1}^2)}{(1-k_{r2}^2)} \quad (4.20) \]

However, by definition

\[ \mathcal{Q} = \frac{m}{V} \quad (4.21) \]

where \( V \) is the total volume of the system.

Then, with (4.21) one can define a system coefficient
\[ c.s. = \frac{d_e l_2 (1 - k r_1^2) l_1 + d_e l_2 (1 - k r_2^2) l_2}{l^3} \]  

(4.22)

This coefficient can be calculated for any initial system configuration and remains constant as long as the mass is kept invariant. Then, for a given physical system it is possible to find the nondimensionalized diameters by using

\[ d_{el}^2 = \frac{1}{l_1 (1 - k r_1^2) + l_2 (1 - k r_2^2)} \sqrt{\frac{E I_2 (1 - k r_1^2)}{(1 - k r_2^2)}} \]  

(4.23)

together with relationship (4.7)

Another useful parameter to analyze the effect of variations of the system geometry is the natural frequency of the corresponding clamped-free system. For the purpose of comparison, W.J. Book (personal communication) based on the nondimensionalization described before and using a transfer matrix model, determined those natural frequencies for different ratios of the stiffness EI and several payloads. The results are shown in Figure 4.7 where

\[ \bar{w} = \frac{w_{clamped}}{w_d} \]  

(4.24)

and the factor \((2/(1 + \sqrt{E I_2/E I_1}))\) corresponds to a correction factor which takes into account the definition of \(w_d\) based upon \(E I_1\). With these elements it is possible to analyze the behavior of a stepped beam under the general rigid gains type of control.
In order to get some insight into the effect of cross section variations, the control method was applied to the system described in Table 4.3 assuming constant length and constant total mass. Two cases were chosen: no payload at all and lumped payload mass of the same order of magnitude as the mass of the total arm.

4.7 No Payload - $\overline{EI_2}$ Variations

In this case the procedure was applied as before for each chosen $\overline{EI_2}$ ratio. The results can be seen in Figure 4.8 for $\overline{EI_2}$ varying from 0.2 to 0.8. As one can notice, if no payload is present, the arm bandwidth becomes better as one decreases the $\overline{EI_2}$ ratio. However, if one uses the results presented in Figure 4.7 it is expected that the best bandwidth for the system would be obtained for $\overline{EI_2}$ ratio equal to 0.045, which corresponds to the maximum clamped-free frequency of the equivalent system. This has not been verified and is included in the suggestions for further work.

4.8 With Payload-$\overline{EI_2}$ Variations

The effect of payload seems to be very important in the search for the best geometry of the system. While an accentuated stepped-beam appears to be the best design for no payload situation, a uniform system looks the best indicated for carrying payloads. This can be seen in Figure 4.9 where the method of general rigid gains was applied in the same way as without payload, for the case of $\overline{m_p} = 1.0$. A close look reveals that the system seems to converge for the best bandwidth when
Values of $\bar{\omega}$ for each case
1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 8.0, 10.0

Figure 4.8 - Root loci of dominant poles - GRG Control stiffness variations, no payload
Values of $\bar{\omega}$ for each case
1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 8.0, 10.0

Figure 4.9 - Root loci of dominant poles - GAG Control
stiffness variations - $\bar{m}_p = 1.0$
$E_2$ approaches 1.0, that is, when the two beams have the same dimensions.

Comparing the maximum reasonable bandwidth with the results from Figure 4.7 it appears that the best results are those for $E_2 = 1.0$, where the system bandwidth is about the natural frequency of the equivalent clamped free system. Also, as was expected for lumped payload, the bandwidth is considerably lower than in the case of no payload. These two sets of results show that the designer should be very careful in specifying the system geometry with respect to the kind of work the arm has to perform. Also it is very important the analysis of the system based upon the payload geometry because of natural frequency reduction caused by the increasing rotary inertia. This fact was not considered in the present work.

4.9 Simon-Mitter Algorithm Applications

At the beginning of the present work, the idea was to apply modal control in order to place the poles of the system at any desired position. However, after a number of applications it was verified that the particular algorithm (SMA) used for the modal control design would not solve the problem due to the fact that poles were moved to positions that did not correspond to minimum sensitivity. As a consequence any small variation that appeared in the process would shift the poles to other locations and even to undesired unstable situations. Once reasonable results were obtained using the general rigid gain method, the idea of applying modal control changed to simply trying to improve the system bandwidth obtained
from rigid gains. Even in this case, if some improvement was obtained it should really be significant in order to compensate for the required measurements and/or estimation of the remaining state variables of the system.

Finally, assuming that a good bandwidth was achieved with the (SMA), the final decision should be made by comparing the required torque with the ones obtained from the application of the other design procedures.

In order to present some results from (SMA) applications the example of Table 4.3 was used with equal beams. Initially the system was assumed with no feedback at all. In terms of pole locations, all poles lay on the imaginary axis with four poles at the origin. As the modal control algorithm was not implemented in this work for applications to cases with repeated eigenvalues, very small gains were assumed in order to disturb numerically the poles at origin. The initial configuration is indicated in Table 4.5 where \( \varepsilon_1 \neq \varepsilon_2 \neq 0 \).

It was shown before that when the general rigid gain method was applied to this system, the best control situation was achieved for the two dominant poles close to the natural frequencies of the clamped-free equivalent system. As this frequency has the value \( \overline{\omega} = 3.52 \), the first movement using the Simon-Mitter algorithm was to shift the two first dominant poles of Table 4.5 to the point \((-3 \pm 3j)\), that is, trying an improvement of about 20% with respect to the rigid method. For comparison, the rigid gain procedure was used in an attempt to obtain similar dominant pole locations. All the eigenvalues are shown in Table 4.6.

Table 4.6 Configuration From General Rigid Gains For Comparison With (SMA)
One important distinction between the two control procedures is that in the case of rigid gains the high frequency poles are free to move during gains variations (Table 4.6) and in case of (SMA) all poles were specified to remain at the same position (Table 4.5) except the ones chosen for relocation. The control is not only acting to move a pair of poles but also to keep the other poles at a fixed position. This fact is displayed very well in Table 4.7 where the gains using both methods for obtaining the same dominant eigenvalues (of Table 4.6) appear in the same order as in expression (4.13). One notices that for the first input to the system the gains corresponding to angular position and velocity feedbacks are smaller in case of (SMA) while for the second input (SMA) appears with bigger gains probably because of the specification of the second dominant pole to a better position than rigid gains gave. On the other hand, due to the fact that the high frequency poles remain constant, (SMA) presents reasonably large linear feedback gains. Again this fact requires high accuracy in the measurements or estimation that must be made to apply the Simon-Mitter technique because of observed high sensitivity of the poles with respect to gain variations.

A second shift using the Simon-Mitter algorithm was performed moving the first dominant poles to \((-5 \pm 5j)\). In this case the modal control gains increased up to 10 times more than those presented in Table 4.7. The rigid gain method cannot yield both dominant poles near this position, so no direct comparison is possible.

Another important effect of the modal control feedbacks, especially
the positive ones, is with respect to system stability. For small motions around the equilibrium position used for control design (shoulder and elbow joints with zero degrees) the linearized model presented stable eigenvalues. However, due to high sensitivity of the poles to parameter variations, the achieved arm bandwidth is rapidly lost as the joint angles change. For gross motion of the elbow joint from 0° to 90° using constant gains obtained by the application of (SMA) at 0°, some high frequency poles change rapidly to the right half complex plane, making the system unstable. This fact was one of the bad characteristics of (SMA) application because for different equilibrium position designs, the gross motion always presented unstable high frequency poles. This fact was not observed using constant gains obtained at the same position using general rigid gains method. As a result, the Simon-Mitter algorithm could not be applied using constant gains for a given gross motion but would only give some improvement for small motions around equilibrium position. This implies that the use of (SMA) for this kind of system would bring some reasonable results only if one has a kind of adaptive modal control. Finally, depending upon the tasks to be performed there is a possibility of controlling the gross motion with the rigid gain method and the fine motion using modal control techniques, using different sets of constant gains.

Table 4.8 Initial Configuration for Sensitivities Application

Let one assume that only angular feedbacks are available for controlling the system. Then, only sensitivities corresponding to eight gains are necessary for analyzing the system despite the fact that all poles must be checked for stability. In order to illustrate the procedure let one consider only the sensitivities of the two poles indicated in Table 4.8. The values of the sensitivities are presented in Table 4.9 and they represent the real and imaginary part of the right hand side of expression (3.30).

Let one assume that a small improvement should be obtained in both poles in the sense of shifting them as close as possible to a damping ratio of $\zeta = 0.707$ while keeping about the same magnitude. From Table 4.9 it is possible to see that pole 1 is much more sensitive to gain variations than pole 2. However, as it would be more desirable to move pole 2 rather than pole 1, it is obvious that one should base the cal-

Table 4.9 Sensitivities of Poles from Table 4.8
calculations upon sensitivities of pole 2. From expression (3.30) and for small variations of the gains, one can write

$$\frac{\Delta \lambda \alpha}{\Delta q_{kj}} = s_{kj}(\alpha)$$  \hspace{1cm} (4.25)

where $s_{kj}(\alpha)$ is the sensitivity of the real (imaginary) part of pole $\alpha$ with respect to variations in the gain $k_{kj}$. Also, if the sensitivity is positive (negative) and the eigenvalue is negative (positive) an improvement in the poles would be obtained by decreasing the corresponding gain and vice versa. If now one turns to Table 4.9 it is verified that the maximum shift of pole two would be obtained for small variations in the gain $k_{17}$. However, for this same gain variations, pole 1 has five times more sensitivity which means it would undergo a bigger shift. It must be kept in mind that this analysis is true only for small variations of the gains since expression (4.25) holds only for linear deviations from the dynamic equilibrium point. Let one assume for example that it was decided to vary gain $k_{17}$ from its original value of -1.873 to a new value -1.9 while the other gains were maintained constant. As one sees, the variation on the gain was about 1.44%. The new pole location is shown in Tables 4.10a and 4.10b.

Table 4.10b  New Poles Using Computer Programs from Appendix A.

As one sees, the predicted values from Table 4.10a are very close to the numbers obtained from the gain variation using the model in a digital computer. The discrepancy observed in the imaginary part of pole 1 might be explained by the fact that the corresponding sensitivity is not constant for the assumed gain variation. The new location is better than the one in Table 4.8 but still is not enough since pole 2 still has a small damping ratio. Further modifications can be obtained by repeating the procedure with the sensitivities calculated for the positions represented in Table 4.10.

In applying the sensitivities procedure for some of the poles, it is also necessary to know what happens with the high frequency eigenvalues since they might go unstable for a desired gain variation to shift a specified pole.

This procedure was applied to several cases in order to improve a few of the poles, especially the dominant ones. However, fair results were obtained only for a large number of trials since the gains variations must be relatively small. For this reason no general results from sensitivities are presented for comparison and the procedure is left only for fine adjustments in a final phase of the design. A more systematic procedure might be designed for computer implementation.

Finally, it should be noticed that sensitivity played a very important role in the present work in the sense of analyzing the numerical results.
obtained. Each time a given set of gains was obtained the sensitivities helped to judge how accurate the gains had to be in order to have only small deviation in the poles corresponding to truncation error. Also in applying the modal control algorithm, sensitivity of the high frequency poles was always analyzed for the purpose of stability because the pole sensitivity may increase considerably when the gains are specified to keep the pole at constant position.

4.11 Comparison of Results with Rigid Gains - No Cross Joint Feedback

In order to show the effect of the cross joint feedback some results obtained in the present work were compared with those obtained by W.J. Book using independent joint feedback and a transfer matrix model of the physical system, as described in [B2]. The values of the gains were obtained from a rigid design technique which yielded a desirable relative position of the four most dominant poles. These gains were presented for the case of equal beams in [B2] and slightly modified to allow for the changes in inertia where the beams are not equal. All results are presented for the non-dimensionalized case of Table 4.3 with changes in the parameters payload and cross section of the component beams. In the case of equal beams ($\overline{EI}_2 = 1.0$) and no payload Figure 4.10 shows the results obtained from no cross joint feedback. Although only one dominant pole is shown, one can see that the maximum arm bandwidth is about 50% of the clamped-free equivalent natural frequency. Variation of the mass distribution of the system from equal beams to a stepped configuration with no payload shows a slight increase in the ratio of arm bandwidth to clamped natural frequency as can be seen from Figure 4.11 ($\overline{EI}_2 = .05$)
No interjoint control

\( \zeta = 0.707 \)

\( \bar{\delta}_p = 0.0 \)

\( ET_1 = ET_2 \)

**Figure 4.10 - Root loci of first dominant pole**

No interjoint feedback, varying \( \omega \)
Figure 4.11 - Root loci of dominant poles - no interjoint feedbacks varying $\bar{w}$, stiffness $EI_2 = 0.05$
and the corresponding plot in Figure 4.7. The effect of payload results in a reduction in this ratio as can be seen in Figure 4.12. These results indicate the importance of the information between the joints. However, as the control has more dynamics the feedback between the joints may cause system instability in case of failure. (The examples of rigid gains are stable even when the cross joint feedback gains are set to zero individually or together).

4.12 The Measurement of Feedback Angles

One observes from the definition of coordinates in the proposed model for the physical system that the angle corresponding to shoulder position ($\theta_1$) can be measured by a simple potentiometer or other type readout. However, for the elbow angle the definition of coordinates requires that not only the rigid angle must be measured but also the slope at the end of the first beam. Here, by rigid angle ($\theta_r$) is meant the angle between the tangent at the end of the first beam and the tangent at the beginning of the second beam that also can be measured by a potentiometer. Measurement of the slope at the end of the first beam is more difficult. In order to present some results comparing the feedbacks measuring the flexible or rigid angle, a brief transformation of coordinates has to be presented. The rigid angle can be defined as

\[ \theta_r = \theta_2 - \phi_{1E}' \]  \hspace{1cm} (4.26)

with

\[ \phi_{1E}' = \phi_{11E} q_{11} + \phi_{12E} q_{12} \]  \hspace{1cm} (4.27)
No interjoint feedback

$\bar{m}_p = 1.0$

$\zeta = 0.707$

$\eta T_2 = 0.22$

Figure 4.12 - Root loci of first dominant pole - no interjoint feedback-varying $\omega$ and fixed payload
where the signs of the components \( \phi_{11E} \) and \( \phi_{12E} \) have been described with respect to the reference frames in Chapter II. Then, in order to use the rigid angle in the feedback law from the general rigid method one must have

\[
\begin{bmatrix}
\xi_1 \\
\xi_2
\end{bmatrix} =
\begin{bmatrix}
K_{T1} & K_{T3} \\
K_{T2} & K_{T4}
\end{bmatrix}
\begin{bmatrix}
\theta_1 \\
\theta_r
\end{bmatrix} +
\begin{bmatrix}
K_{TD1} \\
K_{TD2}
\end{bmatrix}
\begin{bmatrix}
\theta_1 \\
\theta_r
\end{bmatrix}
\]

with the relation of coordinates given by

\[
\begin{bmatrix}
\theta_1 \\
\theta_r
\end{bmatrix} =
\begin{bmatrix}
1 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & -\phi_{11E} & -\phi_{12E} & 0 & 0
\end{bmatrix}
\begin{bmatrix}
\theta_1 \\
\theta_2 \\
q_{11} \\
q_{12} \\
q_{21} \\
q_{22}
\end{bmatrix}
\]

\[
\begin{bmatrix}
\dot{\theta}_1 \\
\dot{\theta}_r
\end{bmatrix} =
\begin{bmatrix}
1 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & -\phi'_{11E} & -\phi'_{12E} & 0 & 0
\end{bmatrix}
\begin{bmatrix}
\dot{\theta}_1 \\
\dot{\theta}_2 \\
\dot{q}_{11} \\
\dot{q}_{12} \\
\dot{q}_{21} \\
\dot{q}_{22}
\end{bmatrix}
\]

Using relations (4.29.1) and (4.29.2) in the proposed model, some results were obtained in order to analyze the effect of the measured angle in the design of the control. In Figure 4.13 one can see the effect of using
Figure 4.13 - Root loci of dominant poles - Rigid and flexible angle definition - variations in payload

$\phi T_2 = 1.0$

1. $\bar{m}_p = 0.0$
2. $\bar{m}_p = 5.0$

Values of $\bar{m}$ for each case:
1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 8.0, 10.0
Figure 4.14 - Root loci of dominant poles - rigid and flexible angle definition - no payload - $ET_2 = 0.045$
the rigid angle in comparison with flexible feedback for the system of Table 4.3 with $\overline{EI}$ ratio equal to unity. The graph shows the results for no payload and for $\overline{m_p} = 5.0$. It is clear that feeding back information about the flexible motion allows the design of a better control. However, the improvement in the arm bandwidth may not justify the considerable complications of measuring the deflection at the end of the first beam. For the case of stepped like system with $\overline{EI_2} = 0.045$ Figure 4.14 shows essentially the same behavior.

4.13 Summary

This chapter presented the general results obtained from the applications of the control techniques presented in Chapter III. A general comparison of the results was presented. Some digital computer simulations applying these results are presented in Chapter V.
CHAPTER V
SIMULATION OF SPECIAL CASES

5.1 General Results

This chapter presents some results from digital simulation of the examples presented in the previous chapter. The results are non-dimensionalized as indicated in Table 4.2 and the main physical characteristics were presented in Figures 4.1 and 4.2. The values of the parameters for nondimensionalization are presented in Table 5.1 for the case of no payload and no joint mass.

Table 5.1 Parameters for Non-Dimensionalization of the Simulated Examples

The simulations are divided into torque impulse responses and parabola tracking performance. The flexible amplitudes are the amplitudes of each mode component, that is, $\ddot{q}_{11}, \ddot{q}_{12}, \ddot{q}_{21}, \ddot{q}_{22}$. The end point dis-
placement means the linear deviation of the end of second beam with respect to the rigid system (\(O_pO_3\) in Figure 2.1).

In order to analyze the behavior of the system under the (SMA) modal control algorithm, Example 2 was chosen for the physical case of zero reference state variables. Following the procedure and results presented in the previous chapters, a control was designed using the general rigid gains method, specifying the dominant poles at 60% of the corresponding clamped-free natural frequency (\(\overline{\omega} = 0.6 \overline{\omega}_c\) where \(\overline{\omega}_c\) is obtained from Figure 4.7). Once the control law was obtained the eigenvalues corresponding to the closed-loop situation were calculated. Then one returned to the original uncontrolled system and applied (SMA) to obtain the closed-loop system with exactly the same eigenvalues as those obtained using the general rigid method. The purpose of this procedure was to compare the response under modal control (SMA) to the response under GRGM and to study the effect of pole sensitivity under both. The results presented in Figures 5.1 and 5.2 correspond to the elbow torque impulse response of the same magnitude. As one can see from Figures 5.1a and 5.2a modal control allows a smaller total angle variation for the elbow but varies the shoulder more. Both systems settle down at about the same time. The oscillatory behavior of modal control at the beginning might be caused by the large number of feedbacks necessary for controlling the system, especially those from the flexible components. From the torque point of view the (SMA) presents a more oscillatory behavior as can be seen from Figures 5.2a and 5.2b.

The maximum torque is bigger in case of modal control, especially
Figure 5.1a - Angle Response of Example 2 for Impulse at Elbow

Figure 5.2e - Flexible Amplitude: Response of Example 2 for Impulse at Elbow
SMA Control for same poles of GRG with $\bar{\omega} = 0.6 \bar{\omega}_C$
at the starting point. Finally, the end point displacement and flexible amplitudes are about twice as large when modal control is applied, as can be seen in Figures 5.1c, 5.1d, 5.2c, 5.2d. Here it is important to notice that the different behavior presented by the system when using modal control algorithm with poles equivalent to the general rigid gains application can be justified by the fact that the eigenvectors are not the same. That is, with the modal control algorithm it is possible to bring the poles to some desired location but it is not necessarily true that the eigenvectors will be the same.

Following the previous results an attempt was made to improve the system response by applying modal control (SMA) to the general rigid gain (Figure 5.2) case and move the two dominant poles to a value of $\bar{W}$ about 2.5 times larger than the case of Figure 5.2 ($\bar{W}$ equals 1.5 of $\bar{W}_c$ the dimensionless clamped-free natural frequency). The remaining poles in this application were not moved. The results for the same impulse response can be seen in Figure 5.3. The angles variations are smaller than the previous case (Figure 5.2) with relatively higher oscillation. Despite the fact that the poles were moved to a position of $\zeta = 0.707$ damping, the sensitivities are so high that as soon as the system starts moving the new pole locations indicate a considerable loss in system damping. The torque history presents about the same maximum as the previous case but acting for a longer period of time. The end point displacement and flexible amplitudes represent a considerable increase from the previous case as can be seen in Figures 5.3c and 5.3d.

Another control was then designed for example 2 using the general
Figure 5.3a - Angle Response of Example 2 for Impulse at Elbow

SMA Control with dominant poles at $\bar{\omega} = 1.5\bar{\omega}_c$
Figure 5.3b - Torque Response of Example 2 for Impulse at Elbow

SMA Control with dominant poles at $\omega = 1.5 \cdot \omega_c$
Figure 5.3d - Flexible Amplitude Response of Example 2 for Impulse at Elbow
SMA Control with dominant poles at $\bar{\omega} = 1.5 \bar{\omega}_c$
rigid gain method. For this situation the gains were obtained by specifying the dominant poles of the rigid system at \( \bar{\omega} = 0.9 \bar{\omega}_c \) of the dimensionless natural frequency of the clamped-free associated system. The results are shown in Figure 5.4a which correspond to a response to torque impulse at the shoulder. The response presents a smooth behavior that is similar to the simulation of a rigid system.

Again for example 2 some gross motion simulations were performed. In all cases the system was supposed to move the elbow angle from \(-15^\circ\) to \(+15^\circ\) according to a double parabola specified as reference input. In Figure 5.4 it is shown the pole variations when the control remains constant and the elbow angle is changed from \(0^\circ\) to \(\pm 90^\circ\). Since the control was designed for \(0^\circ\) elbow angle (the same as in Figure 5.1 with GRG) the arm bandwidth is decreased for working at elbow angle of \(90^\circ\).

If one recalls Figures 5.1 it is seen that the nondimensionalized settling time is of the order of \(\bar{T}_s \approx 3.5\). The system was simulated tracking double parabolas of joint angle \(\theta_2\) of durations \(0.5\bar{T}_s\), \(1.0\bar{T}_s\) and \(2.0\bar{T}_s\) respectively. This set of results can be seen in Figures 5.5, 5.6 and 5.7 and one could say that the recommended time to perform the motion should be set equal to the settling time of the system at zero angle position. With this in mind all the conclusions were applied to the example 2 with \(\bar{\omega} = 0.9\), that is, maximum bandwidth for the general rigid method and settling time from the parabola tracking. The results can be seen in Figure 5.8. It is important to notice that Figure 5.8d represents the flexible components appearing in the system as described in equation (2.36), representing an additional torque generated by the

nonlinearities which in this simulation amounts to only about 10% of the total torque acting in the system.

Finally, Figures 5.9 presents the elbow impulse response of example 1 for $\bar{W} = 0.9 \bar{W}_C$. This case is a more flexible system and this can be noticed by the oscillatory behavior of the response in Figure 5.9b that indicates the system torques have to act in a vibrating way in order to keep decreasing the effect of a higher flexibility.

5.2 Summary

This chapter presented some special simulations using results obtained from the previous chapter. The systems were simulated for the condition of no payload because of large computer time necessary to simulate other configurations. The computer programs are presented in Appendix A and are capable of simulations for any configurations.

CHAPTER VI
CONCLUSIONS AND SUGGESTIONS FOR FURTHER WORK

6.1 Introduction

In this chapter, the principal results of the analysis in this dissertation are summarized. Some conclusions about the proposed model for manipulator arms are presented and the overall results concerning control applications and discussed. Suggestions for future work are given in the final section of this chapter.

6.2 Summary of the Conclusions on the Model

This study has presented a new model of a two-link flexible manipulator arm. The fact that the model introduces the flexible behavior with respect to a hypothetical rigid motion is important in studying overall task performance. The experimental results from an uncontrolled situation have shown that the truncation at the second mode of each flexible component is a good approximation. The generalized coordinates used in this model, regardless of the number of modes chosen, are suitable for obtaining the system configuration at any time \( t \), which would be very helpful from a design point of view.

The fact that the model is presented in a pseudo-standard form \( \dot{\mathbf{x}} = A \mathbf{x} + F(\mathbf{x}, \dot{\mathbf{x}}, t) + B \mathbf{u} \) simplifies the linearization procedure that can be used for application of linear control theory as well as allowing simulations of the controlled nonlinear system. However, if the control law requires more than the simple measuring of jointing angles, the use
of such a model may need more sophisticated techniques for measuring the flexible components.

A more detailed study of the planar motion is also possible by introducing compliance and damping associated with the actuators, for example.

6.3 Control via (SMA)

From the point of view of controlling a flexible manipulator the basic idea of the present work was to design a control technique that could allow high speed without extreme deviations from rigid behavior. This means that the desired flexible position and velocity during the motion should be considered as being zero. With this in mind, this work was started considering the possibility of using one particular modal control algorithm as a means to assign desired closed-loop eigenvalues configuration. However, despite the efforts to obtain desirable results from this technique, the attempts did not present a good control design because specifying the eigenvalues does not necessarily mean that the controlled system has reached a desired situation with respect to the eigenvectors. This fact, related to the non-uniqueness of control law for a multiple-input system, makes the system very sensitive to gains variations which essentially eliminates the possibility of using constant gains for controlling gross motions of manipulators. Even in case of obtaining desirable results from the application of (SMA) in manipulator control there exists the problem of measurement and/or estimation of some state variables present in the system modeling.
6.4 Control Using General Rigid Gains Method

With respect to the rigid like control technique, the addition of cross joint feedback seems to work very well in controlling the flexible system. The application of this method in the present work improved the speed of response by about a factor of two when compared with the control without feedback between the joints. In other words, the arm bandwidth is increased up to the value of the corresponding clamped-free natural frequency. This procedure also eliminates the necessity of flexible measurements and the use of an estimator. Finally, the most important feature of this method is the possibility of working under constant gains since the poles are less sensitive than using (SMA).

This method was applied to controlling the system under different geometric configurations. When a lumped payload mass is present, the results have shown that the arm bandwidth with control decreases compared to the no-payload case. As the payload becomes bigger, the effect of its rotary inertia becomes more and more important. With the increasing of the rotary inertia the associated clamped-free system will have its first natural frequency decreased, consequently reducing the arm bandwidth under control design via rigid gains method.

However, as a wide range of payloads must eventually be considered this work did not deal with all possible alternatives with respect to payload geometry.

It has also been shown in this work that decreasing the relative ratio of stiffness $\overline{EI}_2$ in case of no-payload increases the arm bandwidth. The existence of an optimum stiffness ratio with respect to the clamped-free natural frequency may indicate a limit for improvement in
the closed-loop system performance when this ratio is varied and the system carries no payload or if the payload range is small. On the other hand, it has been shown that for handling large payloads the best indicated ratio is of the order of unity.

6.5 **The Use of Pole Sensitivities to Gains Variations**

The use of pole sensitivity analyses has shown that in most cases it is a matter of finding a set of convenient numbers in order to move the poles to some desirable location. The fact that this process involves a large amount of trials makes it not very useful for the overall design but only for fine adjustments.

6.6 **General Remarks**

In measuring the state of the system it has been shown that the variables included in the proposed model take into account the flexible displacement of the end of the first beam. The improvement in the control when this measurement is used may not justify the complications and accuracy of measuring devices. This means that potentiometer and tachometer measurements may be enough to achieve the desired results using the general rigid gains method.

With respect to system stability, the rigid gains method with cross joint feedbacks and symmetric matrices $K_T$ and $K_{TD}$ presented very good results since the system is always stable. However, if some of the interjoint feedbacks fail, the results have shown that the system remains stable at least for arm bandwidth of order of the clamped-free natural
frequency of the equivalent system. However, despite the loss of desirable response a good safety policy would be to cut all cross feedbacks in case of failure in one of them.

In this work a linearized control technique was applied to a system that in some cases may present severe nonlinear effects. This fact is strongly dependent upon the system itself and this work did not analyze all possible cases of gross motion. In the cases where linear control was applied the results obtained were satisfactory if one considered that the control was designed to keep the system as close as possible to rigid motions. The nonlinear components, as appearing in the equations of the proposed model, act like additional torques and forces to the system during task motions. In the simulations of several cases it was observed that the nonlinear torques amounts to about ten percent of the total torque. However, in cases where the nonlinear effects are significant this effect has to be carefully analyzed.

Finally Table 6.1 summarizes the major results obtained in this work when compared with rigid method cross joint feedback.

6.7 Suggestions for Further Work

The work presented in this dissertation suggests several problems for future investigators:

1. Compare the results obtained with the proposed model with those from a model with only one component mode for each beam;

2. Extend the proposed model to represent spatial motions considering also torsional compliances;
3. Include payloads with large rotary inertia as a third rigid link in the model;

4. Use (SMA) to achieve eigenvalues location such that the sensitivities with respect to gain variations are minimized. This implies in a search for a better relationship for the control components (choice of the arbitrary vector $g_0$ on page 71);

5. Use sensitivity analysis to improve the arm bandwidth by means of a generalized digital procedure;

6. Examine with some detail the effect of nonlinearities due to the motion as well as torque limitations imposed by the actuators;

7. Examine the possibility of controlling gross motions and fine motions with different control procedures by using different regions of constant gains.

APPENDIX B

B.1 Modal Decomposition Property \([S2]\)

This property is better introduced through an example. Suppose the representation (3.4.1) with \(n=4\) and assume poles 1 and 3 have to be changed. Then the control law \(u\) becomes:

\[
u = g_1 z_1 + g_3 z_3 \tag{1.B}\]

where \(g_1\) and \(g_3\) are \(r\)-dimensional vectors. Then \(\bar{A}\) is given by

\[
\bar{A} = \begin{bmatrix}
\lambda_1 + \delta_{11} & 0 & \delta_{13} & 0 \\
\delta_{21} & \lambda_2 & \delta_{23} & 0 \\
\delta_{31} & 0 & \lambda_3 + \delta_{33} & 0 \\
\delta_{41} & 0 & \delta_{43} & \lambda_4
\end{bmatrix} \tag{2.B}
\]

Using properties for interchanging rows and columns of determinants (2.B) yields to

\[
\det(sI - \bar{A}) = \det
\begin{bmatrix}
s - \lambda_1 - \delta_{11} & -\delta_{13} & 0 & 0 \\
-\delta_{31} & s - \lambda_3 - \delta_{33} & 0 & 0 \\
-\delta_{21} & -\delta_{23} & s - \lambda_2 & 0 \\
-\delta_{41} & -\delta_{43} & 0 & s - \lambda_4
\end{bmatrix} \tag{3.B}
\]

On the other hand, if \(A_{11}\) and \(A_{22}\) are square matrices
\[
\text{det} \begin{bmatrix}
A_{11} & A_{12} \\
0 & A_{22}
\end{bmatrix} = \text{det} (A_{11}) \cdot \text{det} (A_{22})
\] (4.B)

Using (4.B) into (3.B) one finally has

\[
\text{det}(sI - \Delta) = (s - \lambda_2)(s - \lambda_4) \cdot \text{det}
\begin{bmatrix}
s - \lambda_1 - \delta'_{11} & -\delta'_{13} \\
-\delta'_{31} & s - \lambda_3 - \delta'_{33}
\end{bmatrix}
\] (5.B)

B.2 Useful Identity for Inversion of a Complex Matrix with Complex Conjugated Columns

Let

\[
A = \begin{bmatrix}
a_{11} + b_{11}j & a_{11} - b_{11}j & c_{11} \\
a_{21} + b_{21}j & a_{21} - b_{21}j & c_{21} \\
a_{31} + b_{31}j & a_{31} - b_{31}j & c_{31}
\end{bmatrix}
\] (6.B)

If one finds

\[
\begin{bmatrix}
a_{11} & b_{11} & c_{11} \\
a_{21} & b_{21} & c_{21} \\
a_{31} & b_{31} & c_{31}
\end{bmatrix}^{-1} = \begin{bmatrix}
a_{11} & a_{12} & a_{13} \\
\beta_{11} & \beta_{12} & \beta_{13} \\
\gamma_{11} & \gamma_{12} & \gamma_{13}
\end{bmatrix}
\] (7.B)
Then

\[
A^{-1} = \begin{bmatrix}
\frac{a_{11} - \beta_{11}}{2} j & \frac{a_{12} - \beta_{12}}{2} j & \frac{a_{13} - \beta_{13}}{2} j \\
\frac{a_{11} - \beta_{11}}{2} & \frac{a_{12} - \beta_{12}}{2} & \frac{a_{13} - \beta_{13}}{2} \\
\gamma_{11} & \gamma_{12} & \gamma_{13}
\end{bmatrix}
\]
APPENDIX C

NONDIMENSIONALIZED PARAMETERS OF EXAMPLES 1 AND 2

Procedure for nondimensionalization

1 - Determine parameters for nondimensionalization described in Table 4.1

2 - Determine ratios \( k_{r1} \) and \( k_{r2} \) using equations (4.5) and (4.6)

3 - If \( EI_1 \neq EI_2 \) determine system coefficient c.s from equation (4.22) and find the diameters using \( k_{r1} \), \( k_{r2} \) and equations (4.23) and (4.7.2)

4 - Equations (4.11) and (4.12) determine the nondimensionalized parameters \( \overline{\mu}_1 \) and \( \overline{\mu}_2 \)

Tables C.1 and C.2 present the nondimensionalized parameters for Examples 1 and 2.
