1 Introduction

This document is a report about the capabilities and performance of the IOA Toolkit, and in particular the tools that provide support for implementing and running distributed systems (checker, composer, code generator). The Toolkit compiles distributed systems specified in IOA into Java classes, which run on a network of workstations and communicate using the Message Passing Interface (MPI). In order to test the toolkit, several distributed algorithms were implemented, ranging from simple algorithms such as LCR leader election in a ring network to more complex algorithms such as the GHS algorithm for computing the minimum spanning tree in an arbitrary graph. All of our experiments completed successfully, and several runtime measurements were made.

2 Experiments

Implementation Platform The machines used are located in the Theory of Computation Group of the MIT Computer Science and Artificial Intelligence Laboratory, forming a Local Area Network. They are all Red Hat Linux machines and with Intel Pentium III to IV with clock speed ranging from 1 GHz to 3.2 GHz. Even though MPI sets up a connection between every pair of nodes, the algorithms only use the communication channels they need. For example, a node (i) in LCR only sends to node i+1 and only receives from node i-1.

2.1 LCR Leader Election

The algorithm of Le Lann, Chang and Roberts for Leader Election in a ring network was the first experiment in running an IOA program on a network of computers. The automaton definition that appears in [1](Section 15.1) was used, with some modifications. For all the algorithms that follow, the nodes are automatically numbered from 0 to (size - 1).

Automata Definitions The automata LCRProcess, LCRNode, SendMediator and ReceiveMediator were written. The mediator automata are given in Appendix C.1 (these automata implement the channel automata integrated with MPI functionality). The composed automaton (LCR) appears in Appendix C.2 (this is the one that is translated into Java code by the IOA Toolkit).

LCR Leader Election process automaton

type Status = enumeration of idle, voting, elected, announced

automaton LCRProcess(rank: Int, size: Int)
signature
    input vote
    input RECEIVE(m: Int, const mod(rank - 1, size), const rank: Int)
    output SEND(m: Int, const rank: Int, const mod(rank+1, size))
output leader(const rank)

states
  pending: Mset[Int] := {rank},
  status: Status := idle

transitions
  input vote
    eff status := voting
  input RECEIVE(m, j, i) where m > i
    eff pending := insert(m, pending)
  input RECEIVE(m, j, i) where m < i
  input RECEIVE(i, j, i)
    eff status := elected
  output SEND(m, i, j)
    pre status ≠ idle ∧ m ∈ pending
    eff pending := delete(m, pending)
  output leader(rank)
    pre status = elected
    eff status := announced

LCR Leader Election composition automaton

automaton LCRNode(rank: Int, size: Int)
  components
  P: LCRProcess(rank, size);
  RM[j:Int]: ReceiveMediator(Int, Int, j, rank)
    where j = mod(rank-1, size);
  SM[j:Int]: SendMediator(Int, Int, rank, j)
    where j = mod(rank+1, size)

Results The trace of a run on 8 nodes (on 4 machines) can be found in Appendix E.1. A snapshot of the trace, representing the last five transitions, is shown below.

A snapshot of the trace of LCR leader election

transition: output SEND(7, 5, 6) in automaton LCR(5)
on condor.csail.mit.edu at 7:25:37:280
Modified state variables:

transition: output RECEIVE(7, 5, 6) in automaton LCR(6)
on parrot.csail.mit.edu at 7:25:37:755
Modified state variables:
P → Tuple, modified fields: {[pending -> (7)] }

transition: output SEND(7, 6, 7) in automaton LCR(6)
on parrot.csail.mit.edu at 7:25:37:770
Modified state variables:
P → Tuple, modified fields: {[pending -> ()] }
SM → Map, modified entries: {[7 -> Tuple, modified fields: {[tosend ->
As the trace indicates, node 7's message has made its way around the ring and eventually returned to node 7. At that point, node 7 announced itself as the leader. Figure 2.1 shows the messages sent by the nodes. All messages were sent from node 0 to node 4 (mod 8) and the message with value i was sent first. The message with value 7 followed and made the round of the ring, to elect node 7 as the leader.

![Diagram of the LCR leader election algorithm on a ring of 8 nodes.](image)

Figure 2.1: Running the LCR leader election algorithm on a ring of 8 nodes. The white squares represent the nodes, while the shaded parallelograms represent the messages sent.

### 2.2 Asynchronous Spanning Tree

The Asynchronous Spanning Tree Algorithm, (see Section 15.3 of [1]) was the next test for the Toolkit. The algorithm is still very simple: Given a general graph it computes a spanning tree on the graph. This was the first test of the Toolkit on arbitrary graphs, where each node had more than one incoming and outgoing communication channels.

**Automata Definitions** The AsyncSpanningTree automaton, as defined in [1](Section 15.3) was used. The process automaton and the composition one are listed below. The expanded automaton is shown in Appendix C.3.
Asynchronous Spanning Tree process automaton

type Message = enumeration of search, null

automaton sTreeProcess(i: Int)
signature
    input RECEIVE(m: Message, const i: Int, j: Int)
    output SEND(m: Message, const i: Int, j: Int)
    output PARENT(j: Int)

states
    nbrs: Set[Int] := {},
    parent: Int := -1, % -1 for null
    reported: Bool := false,
    send: Map[Int, Message]

transitions
    input RECEIVE(m, i, j)
    eff
        if i ≠ 0 ∧ parent = -1 then
            parent := j;
            for k: Int in nbrs - {j} do
                send[k] := search
            od
        fi
    output SEND(m, i, j)
    pre send[j] = search
    eff send[j] := null
    output PARENT(j)
    pre parent = j ∧ reported = false
    eff reported := true

Asynchronous Spanning Tree composition automaton

type Message = enumeration of search, null

automaton sTreeNode(i: Int)
    components
        P: sTreeProcess(i);
        RM[j: Int]: ReceiveMediator(Message, Int, i, j);
        SM[j: Int]: SendMediator(Message, Int, i, j)

Results  Figure 2.2 shows a graph of 16 nodes connected in a 4 × 4 grid that was used on some of our tests. The source node was node 0. Some of the spanning trees computed are also shown in Figure 2.2. A snapshot of the trace follows, showing nodes 1 and 4 sending their message to node 5. The message of node 1 arrives first and thus node 5 announces node 1 as its parent. The complete trace of this run can be found in Appendix E.2.

Trace snapshot of the Asynchronous Spanning Tree algorithm
Figure 2.2: The $4 \times 4$ grid used to test the Asynchronous Spanning Tree Algorithm, along with 2 different spanning trees computed from 2 different runs of the algorithm.

   ioa.runtime.adt.MapSort]
2.3 Asynchronous Broadcast Convergecast

This is essentially an extension of the previous algorithm, where along with the construction of a spanning tree, a broadcast and convergecast take place (using the computed spanning tree). The source node was node 0, and the message 99 (a dummy message) was broadcast on the network. Some complexity is added compared to the previous algorithm by the fact that different kinds of messages are exchanged.

Automata Definitions The AsynchBcastAck automaton, as defined in [1](section 15.3) was used. The process automaton and the composition automaton are shown below. The expanded automaton is given in Appendix C.4.

Asynchronous Broadcast Convergecast process automaton

```plaintext
type Kind = enumeration of bcast, ack
type BCastMsg = tuple of kind: Kind, w: Int
type Message = union of msg: BCastMsg, kind: Kind

automaton bcastProcess(rank: Int, nbrs: Set[Int])
signature
  input RECEIVE(m: Message, const rank, j: Int)
  output SEND(m: Message, const rank, j: Int)
  internal report(const rank)

states
  val: Int := -1, % -1 = special value denoting null
  parent: Int := -1,
  reported: Bool := false,
  acked: Set[Int] := {},
  send: Map[Int, Seq[Message]]

initially
  rank = 0 ⇒
  (val = 99 ∧ % 99 = the value to be broadcast
  (∀ j: Int
   ((j ∈ nbrs) ⇒ send[j] = {} ⊢ msg([bcast, val]))))

transitions
  output SEND(m, rank, j)
  pre m = head(send[j])
  eff send[j] := tail(send[j])
  input RECEIVE(m, rank, j)
  eff
    if m = kind(ack) then
      acked := acked ∪ \{j\}
    else
      if val = -1 then
        val := m.msg.w;
        parent := j;
        for k:Int in nbrs - \{j\} do
          send[k] := send[k] ⊢ m
        od
      else
        send[j] := send[j] ⊢ kind(ack)
```

7
internal report(rank) where rank = 0
pre acked = nbrs;
reported = false
eff reported := true
internal report(rank) where rank ≠ 0
pre parent ≠ -1;
acked = nbrs - {parent};
reported = false
eff send[parent] := send[parent] ⊕ kind(ack);
reported := true;

Asynchronous Broadcast Convergecast composition automaton

type Message = union of msg: BCastMsg, kind: Kind

automaton bcastNode(i: Int)
  components
    P: bcastProcess(i);
    RM[j: Int]: ReceiveMediator(Message, Int, i, j);
    SM[j: Int]: SendMediator(Message, Int, i, j)

Results  The algorithm was tested on several graphs. One of them is shown in Figure 2.3 (a).
Figure 2.3 (b) and (c) depicts some of the spanning trees that were computed and the communi-
tication sequence; the numbers next to the nodes represent the sequence at which the nodes
reported done (through the internal report action). A snapshot of the trace is listed below, showing
nodes 1 and 4 reporting that they are done. At that point, node 0 is enabled and after some commu-
ication between these nodes, node 0 also reports done. The complete trace of this run is shown in
Appendix E3.

Trace snapshot of the Asynchronous Broadcast Convergecast algorithm

transition: internal report(1) in automaton bcastNode
Modified state variables:
P → [val: 99, acked: (2 5), nbrs: (0 2 5), parent: 0, reported: true,

2.4 Leader Election Using Broadcast Convergecast

In page 500 of [1], the author describes how the Asynchronous Broadcast Convergecast algorithm can be used to implement a leader election algorithm on a general graph using the Asynchronous Broadcast Convergecast algorithm. The main idea is to have every node act as a source node and create its own spanning tree, broadcast its UID using this spanning tree and hear from all the other nodes via a convergecast. During this convergecast, along with the acknowledge message, the children also send what they consider as the maximum UID in the network. The parents gather the maximum UIDs from the children, compare it to their own UID and send the maximum to their own parents. Thus, each source node learns the maximum UID in the network and the node whose UID equals the maximum one announces itself as a leader.

Automata Definitions The process and composition automata are shown below. The expanded automaton is defined in Appendix C.5.

**Leader Election Using Broadcast Convergecast process automaton**

```plaintext
type Kind = enumeration of bcast, ack

type BCastMsg = tuple of kind: Kind, w: Int

Leader Election Using Broadcast Convergecast composition automaton

automaton bcastLeaderNode (i: Int)
  components
    P: bcastLeaderProcess (i);
    RM[j: Int]: ReceiveMediator (Message, Int, i, j);
    SM[j: Int]: SendMediator (Message, Int, i, j)
2.5 Unrooted Spanning Tree to Leader Election

The algorithm STtoLeader of [1](page 501) was implemented as the next test for the Toolkit. The algorithm takes as input an unrooted spanning tree and returns a leader. The automaton listed below was written, according to the description of the algorithm.

Automata Definitions The process and composition automata are listed below, while the expanded automaton can be found in Appendix C.6.
Unrooted Spanning Tree to Leader Election process automaton

\begin{verbatim}

type Status = enumeration of idle, elected, announced

type Message = enumeration of elect

axioms ChoiceSet(Int for E)

automaton sTreeLeaderProcess(rank: Int, nbrs:Set[Int])

signature

  input RECEIVE(m: Message, const rank: Int, j: Int)
  output SEND(m: Message, const rank: Int, j: Int)

output leader

states

  receivedElect: Set[Int],
  sentElect: Set[Int],
  status: Status,
  send: Map[Int, Seq[Message]]

initially

  true ⇒

  receivedElect = {}
  ∧ sentElect = {}
  ∧ status = idle
  ∧ (size(nbrs) = 1 ⇒
        send[chooseRandom(nbrs)] = send[chooseRandom(nbrs)] ⊢ elect)

transitions

  input RECEIVE(m, i, j)
    eff receivedElect := insert(j, receivedElect);
    if size(receivedElect) = size(nbrs) - 1 then
        send[chooseRandom(nbrs - receivedElect)] :=
        send[chooseRandom(nbrs - receivedElect)] ⊢ elect;
        sentElect :=
        insert(chooseRandom(nbrs - receivedElect), sentElect)
    elseif receivedElect = nbrs then
        if j ∈ sentElect then if i > j then status := elected fi
        else status := elected
    fi
    fi

  output SEND(m, i, j)
      pre m = head(send[j])
      eff send[j] := tail(send[j])

output leader

      pre status = elected
      eff status := announced

\end{verbatim}

Unrooted Spanning Tree to Leader Election composition automaton

\begin{verbatim}

automaton sTreeLeaderNode(rank: Int, nbrs:Set[Int])

components

  P: sTreeLeaderProcess(rank, nbrs);
  RM[j:Int]: ReceiveMediator(Message, Int, rank, j);
  SM[j:Int]: SendMediator(Message, Int, rank, j)

\end{verbatim}

Results  The algorithm was tested on several graphs and different spanning trees as input. A spanning tree on a 4 × 4 grid is shown in Figure 2.4. The algorithm worked correctly, announcing
only one node as the leader. A snapshot of the trace is listed below. In that specific run, the edge between nodes 5 and 6 had elect messages sent in both directions; with node 6 being elected as the leader, having a larger UID. The complete trace of this run can be found in Appendix E.4.

Figure 2.4: (a) shows the unrooted spanning tree used in one run. In (b), the arrows show the direction of the messages in a specific run, where the edge between nodes 5 and 9 had elect messages sent in both directions. Node 9, with a larger UID was elected as the leader.

2.6 GHS Minimum Spanning Tree

The last algorithm we ran using the Toolkit was the algorithm of Gallager, Humblet and Spira for
finding the minimum-weight spanning tree in an arbitrary graph. Welch, Lamport and Lynch give
an I/O automaton definition of the GHS algorithm in [2], which is used as a basis for our automata
definitions. One technical detail in running this version of the algorithm is that the edge weights
needed to be unique. This algorithm is significantly longer than the previous ones, with 7 different
messages exchanged and 12 state variables for each automaton.

Automata Definitions The automaton below defines the algorithm and the composition with
the mediator automata is shown after that. The expanded automaton can be found in App-
endix C.7.

GHS process automaton

type Nstatus = enumeration of sleeping, find, found
type Edge = tuple of s: Int, t: Int
type Link = tuple of s: Int, t: Int
type Lstatus = enumeration of unknown, branch, rejected
% Message Types
type Msg = enumeration of CONNECT, INITIATE, TEST, REPORT, ACCEPT,
             REJECT, CHANGEROUT
type ConnMsg = tuple of msg: Msg, l: Int
type Status = enumeration of find, found
type InitMsg = tuple of msg: Msg, l: Int, c: Null[Edge], st: Status
type TestMsg = tuple of msg: Msg, l: Int, c: Null[Edge]
type ReportMsg = tuple of msg: Msg, w: Int
type Message = union of connMsg: ConnMsg, initMsg: InitMsg,
                 testMsg: TestMsg, reportMsg: ReportMsg,
                 msg: Msg

uses ChoiceSet(Link)

GHS composition automaton

20
Results  One of the graphs that were used to test the algorithm is shown in Figure 2.5 (a). The (unique) minimum spanning tree computed by the algorithm is shown in Figure 2.5 (b). A snapshot of the trace follows, showing the beginning of the algorithm with node 0 waking up (after a `start` action), sending a `CONNECT` message to its minimum weight outgoing edge (1) and reporting this edge as part of the minimum spanning tree. The complete trace of this run can be found at http://theory.csail.mit.edu/~pmavrom/ioaReport.html. The algorithm ran correctly, returning the unique minimum spanning tree in all cases.

Figure 2.5: (a) shows one of the graphs used to test the GHS algorithm. In (b), the (unique) minimum spanning tree computed by the algorithm.

Trace snapshot of the GHS algorithm

3 Results

Figures 3.6, 3.7 and 3.8 depict the runtime results of the algorithms on 1 node per machine, a constant number of nodes and a constant number of machines respectively. The runtimes were measured in seconds, from the time when the first node started initialization until the time at which the algorithm terminated, and they are averages on 10 runs. The tables in Appendix D show the raw data collected from our experiments. In Figure 3.6(a) to (b) the relationship between time and number of nodes is not very clear due to the short time taken, number of nodes and messages exchanged. Figure 3.6(d) however, where the number of messages exchanged is large shows the clear (linear) relation.

4 Conclusions

During the months of June and July 2004 we had the opportunity to test the capabilities and the performance of the version of the toolkit that was then available. We started by mostly modifying the Java code the Toolkit generated to get LCR up and running. The toolkit was then gradually modified to automate the manual changes we had to make in Java. By the Spanning Tree to Leader algorithm the Toolkit was completely automated to provide Java code that compiled and ran successfully. After that, and after making sure that simple algorithms such as a simple broadcast and convergecast could run, we implemented a more complicated algorithm, the GHS algorithm for computing the minimum spanning tree in an arbitrary graph. The successful implementation of this algorithm makes us very confident that the toolkit can be used to implement complex distributed systems successfully.

Performance  We now comment on some performance issues:

1. Scalability: As Figure 3.6 suggests, the Toolkit is scalable. Letting the number of nodes double increases the runtime but no more than twice the previous runtime. Moreover, Figure 3.6(e) shows that the rate of increase of the running time is smaller as the number of messages increases.

2. Setup time: The time required for MPI to set up all the connections and enable the nodes to initialize was not measured in the runtime results. However, when the number of nodes was large, this time was also quite significant (around 5-10 minutes).

3. Resource usage: The generated programs used all the available processing power available to them during the whole run. This was mainly because there was no pause between successive tests for incoming or outgoing messages.

5 Comments and Suggestions on the Toolkit

- The NDR Language, used both in the scheduler and the initialization block could be extended to support the for v:T in s:Set[T] statement, which is already used in IOA. This would make the code much cleaner since using the current syntax, these loops are implemented using a while loop and an extra set of two or more variables.
Figure 3.6: (a) to (d) show the time taken to complete the algorithm in regard to the number of nodes. (e) shows the time of Broadcast Leader Election in regard to the number of messages exchanged.
Figure 3.7: (a) to (c) show the time taken to terminate, in regard to the number of physical machines used.
Figure 3.8: (a) to (c) show the time taken to terminate, in regard to the number of nodes.
Initialization of Map (or Array) entries. The toolkit allows usage of possibly non-initialized map/ array entries. As a result, when the compiled code is run, a NullPointerException is thrown from the Java environment when these variables are accessed. The following example illustrates the problem and demonstrates some possible solutions:

```java
type Tup = tuple of a: Int, b: Bool

automaton Test
signature
...
states
M: Map[Tup]
initially
(truth ⇒ SM[1].a = 3)
det do
SM[1].a := 3
...
```

The user here tries to initialize the tuple before constructing it, which is done using a command like `SM[1] := [3, truth]`. One possible solution would be for the toolkit to check for an initialization statement of the type `SM[1] := ...` in the `initially` block, before the accessing statement (of the type `SM[1].a`). If none exists, it could print a warning. Another solution could be to arbitrarily initialize all Map / Array Entries. The toolkit already supports such kind of initialization, but again if it does not occur, a warning message could be printed.

- In GHS, some parts of the IOA code were used more than once. The code given in [2] makes use of a `procedure`, i.e. a block of statements that can be declared and then called as many times as necessary. Given the complexity of GHS, such a feature would be quite useful during the design, coding and debugging process. For GHS, there was no need for parameter passing to the procedure. Therefore, as a first step, a simple procedure support (without parameter passing) from the toolkit would be enough.

- The use of MPI for communication has both advantages and disadvantages. Implementing the Toolkit was probably easier using MPI. No low-level communication programming was necessary. Furthermore, it has been tested to work for a long time now, and indeed, it works. However, it introduces some issues that could have been avoided. Firstly, most of the error messages coming from MPI are far from descriptive. (see Troubleshooting #4) Moreover, MPI sets up a connection between all pairs of nodes, even if these connections are not necessary. An n-node LCR needs only n connections, while MPI sets up Θ(n²) connections. This is probably the reason why on a larger number of nodes, MPI takes up a lot of time to setup. We suggest that the possibility of another communication interface, which gives more control over these issues (e.g. Java RMI) is examined at some time in the future.

- Finally, we have tested the possibility of pausing between consecutive tests for incoming and outgoing messages (MPI's `test` and `Iprobe`). Right now a node might be in an infinite loop probing for messages for tens of seconds and using up all the processing power available to it. Forcing the nodes to sleep for some milliseconds before probing again showed to improve performance when the number of nodes per physical machine is large. We have experimented with some runtimes of LCR. Leader election on 20 nodes on a single machine, using different sleep times. The results are shown below:
<table>
<thead>

References

A Troubleshooting

1. Sometimes during the composition of the process and mediator automata, two SEND and/or two RECEIVE transitions were produced by the composer. This should be fixed before generating Java code because the code will not compile later. To prevent this one should make sure that the where clauses on the SEND and RECEIVE actions in the process automaton match the where clauses for the SendMediator and ReceiveMediator component automata in the node composition.

2. Send/Receive Convention. In LCR, we have used the convention of \[1\] for the Send and Receive transitions: Send(m, i, j) and Receive(m, j, i). This means that i is always the sender and j is always the receiver. This convention sometimes caused problems that were hard to debug. We found that using a different convention made it easier to understand and debug any problems: Send(m, i, j) and Receive(m, i, j), meaning that node i sends to node j and node i receives from node j respectively.

3. Currently the NDR Language, used in the schedule and initially blocks does not support the for v:T in S:Set[T]. The way to create such loops is to use a while loop of the form:

uses ChoiceSet

...

schedule
states
  tempNbrs: Set[Int],
  k: Int

do
  tempNbrs := P.nbrs;
  while (~isEmpty(tempNbrs)) do
    k := chooseRandom(tempNbrs);
    tempNbrs := delete(k, tempNbrs);
    \% fire action on neighbor k
  od;
od

4. MPI throws a SIGSEV error if the program tries to access a node using a negative number as the rank.

5. Several times when running an algorithm we encountered a java.lang.NullPointerException during the initialization or the first transitions of the automata. Almost always, this was due to a wrong initialization of the state variables in IOA.

B Bug Reports

1. In the LCRNode automaton some types such as Status and .States[LCRProcess] were not declared automatically. Manual declaration of these types was necessary. The latest version
of the toolkit generates these type definitions automatically. [Fixed]

2. The transitions that connect to the MPI have different signatures, but the implementation of the toolkit did not support that. (e.g. Iprobe(i_v1, j_v2) and resp_Iprobe(i_v3, j_v4) were not recognized as an MPI pair). We manually changed them to have exactly the same signature, for example Iprobe(i_v1, j_v2) and resp_Iprobe(i_v1, j_v2). The latest version of the toolkit recognizes them as pairs even if they have different names. [Fixed]

3. In LCR a statement (const 0) was produced that was not recognized by the code generator. We manually changed the C file produced to (const v999), and declared the variable v999 to something like (v999 zero s8 (scope 1)) where s8 was the sort corresponding to NatSort. [Pending]

4. Formal parameters were not translated in Java. We manually declared the field in the generated code, and initialized it to the correct value. The toolkit now translates all formal parameters and automatically initializes three special parameters: rank, size (of type int or Nat) and hostName (of type String). [Fixed]

5. The initialization of the arguments from MPI (the statement MPI.Init(args);) had to happen in the main() method of the class LCRNode and not in the runtime Automaton. Otherwise, the environment would not recognize the correct number of processes running. The toolkit has been modified so that this will happen automatically from now on. [Fixed]

6. The composer tool (incorrectly) removes all the preconditions of internal actions during composition. [Pending]

7. In the NDR Language translation, no break; statement was produced after a fire block. This caused unexpected termination in some algorithms. [Fixed]

8. IntSort’s modulo operator is not compatible with its specification. [Pending]

9. The syntax of declaring a map is v: Map[d1, ..., dn, r] where n ≥ 1. If only one type is given, (e.g. map: Map[Int]), the checker tool throws a java.lang.InternalError instead of a more descriptive Syntax Error message.
C  Automata Definitions and Input Files

C.1  SendMediator and ReceiveMediator

These automata were used as the channel between two nodes and the connection of the automata
to the MPI.

SendMediator

\[\text{type sCall = enumeration of idle, Isend, test}\]

automaton SendMediator(Msg, Node_Type, i:Node, j:Node)

    assumes Infinite(Handle)

    signature
    input SEND(m: Msg, const i, const j)
    output Isend(m: Msg, const i, const j)
    input resp_Isend(handle:Handle, const i, const j)
    output test(handle:Handle, const i, const j)
    input resp_test(flag:Bool, const i, const j)

    states
    status: sCall := idle,
    toSend: Seq[Msg] := {},
    sent: Seq[Msg] := {},
    handles: Seq[Handle] := {}

    transitions
    input SEND(m, i, j)
    eff toSend := toSend ⊕ m
    output Isend(m,i,j)
    pre head(toSend) = m;
    status = idle
    eff toSend := tail(toSend);
    Sent := sent ⊕ m;
    status := Isend
    input resp_Isend(handle, i, j)
    eff handles := handles ⊕ handle;
    status := idle
    output test(handle, i, j)
    pre status = idle;
    handle = head(handles)
    eff status := test
    input resp_test(flag, i, j)
    eff if (flag = true) then
        handles := tail(handles);
        sent := tail(sent)
    fi;
    status := idle

ReceiveMediator

\[\text{type rCall = enumeration of idle, receive, Iprobe}\]
automaton ReceiveMediator(Msg, Node: Type, i: Node, j:Node)

assumes Infinite(Handle)

signature
output RECEIVE(m:Msg, const i, const j)
output Iprobe(const i, const j)
input resp_Iprobe(flag:Bool, const i, const j)
output receive(const i, const j)
input resp_receive(m: Msg, const i, const j)

states
status: rCall := idle,
toRecv: Seq[Msg] := {},
ready: Bool := false

transitions
output RECEIVE(m, i, j)
  pre m = head(toRecv)
  eff toRecv := tail(toRecv)
output Iprobe(i, j)
  pre status = idle;
     ready = false
  eff status := Iprobe
input resp_Iprobe(flag, i, j)
  eff ready := flag;
     status := idle
output receive(i, j)
  pre ready = true;
     status = idle
  eff status := receive
input resp_receive(m, i, j)
  eff toRecv := toRecv |- m;
     ready := false;
     status := idle

--------------------------------------

C.2 LCR

Expanded automaton with initialization and scheduling

uses ChoiceSet(Int)

automaton LCR(rank: Int, size: Int)
signature
output receive(N6: Int, N7: Int)
  where N7 = rank ∧ N6 = mod((rank+size) -1, size)
output SEND(m: Int, I2: Int, I3: Int)
  where I3 = mod(rank + 1, size) ∧ I2 = rank
