ROUNDED BRANCH AND BOUND METHOD FOR
MIXED INTEGER NONLINEAR PROGRAMMING PROBLEMS

Jacob Akoka

WP 904-77 January 1977
ABSTRACT

Most of the research in the field of integer programming has been devoted to the case of integer linear programming. When one has to deal with non-linearities, linearization techniques are used. But these techniques are not general enough to be applied to all the varieties of non-linearities. Besides, the techniques add more variables to the original problem, making large-scale problems very difficult to solve.

In this paper, a method is described to solve integer nonlinear programming problems. In this "bounded Branch and Bound" method, the arborescence has only N nodes, where N is the number of variables of the problem. Therefore, we store in the main memory of the computer only the informations relative to the N nodes. We can therefore solve large-scale integer nonlinear programming problems.

When the objective function and the constraints are convex, a procedure is given, which enables us to alleviate the arborescence. For non-convex problems, a specific method is described. While optimizing a problem of the arborescence, some "fortuitous integer variables" may appear. A procedure is described to schedule these variables. Our method is also specialized to the case of Boolean variables.

Five different criteria which enable us to chose the "separation variable" are described and ordered. Finally, a programming code was written in Fortran IV. We report the results obtained using this code. The CPU times necessary to solve the problems are very small. We can therefore expect to solve large-scale integer nonlinear programming problems in reasonable time.
INTRODUCTION

In this paper, we describe a method, called Bounded Branch and Bound method, which enables us to solve mixed (or pure) Integer Nonlinear Programming problems. The formulation of the problem is:

\[
\begin{align*}
\text{Max } & \  \phi(x) \quad x \in \mathbb{R}^n \\
\text{Subject to } & \  \ \ \\
h_{j}(x) & \leq 0 \quad j = 1, 2, \ldots, m \tag{c-1}
\end{align*}
\]

\[
\begin{align*}
a_j & \leq x_j \leq b_j \quad j \in J = 1, 2, \ldots, n \tag{c-2}
\end{align*}
\]

\[
\begin{align*}
x & \text{ integer } \quad j \in E \cap J \tag{c-3}
\end{align*}
\]

In (I-1), we give a brief outline of the Bounded Branch and Bound method.

A procedure to construct an oriented graph associated with the problems is described in (I-2). In (I-3), we develop a specific graphical language for the arborescence, and in (I-4) we describe 6 different rules which are to be used in the arborescence. Depending on the rule used, each node change from one state to another one. The transformation table is given in (I-5).

A detailed procedure describing the passage from node s to node t is given in (I-6). If the problem is convex (i.e. the objective function and the constraints are convex), two properties are developed. The first one allows us to refuse a node of the arborescence without investigation. The second one enables us to stop the optimization process of a problem before the end. These techniques are described in (I-7).
In (I-8), we relax the assumption that the problem is convex. Therefore, we develop a specific algorithm for the non-convex case. Some modifications are indicated in (I-9), in order to solve the case where all the variables are boolean.

At each node of the arborescence, we will have to solve a continuous nonlinear programming problem. When solving this problem some variables may become integer. Such variables are called "fortuitous integer variables" (fiV). A procedure to schedule these variable is developed in (I-10). At each node, we will have to choose a variable to become integer. Such variable is called the "separation variable". Five different criteria are given, in order to choose this variable (I-11). A proof of the convergence of the algorithm is given in (I-12) and in (I-13) we indicate the number of nodes to be stored in the main memory of the computer. In (I-14) we give a complete example.

In chapter II, we describe the numerical computations. Ten different problems have been solved using BBB and the five different criteria developed precedingly (II-1). In (II-2), we describe three different methods which enable us to order the five criteria. In (II-3), we present a flowchart of the computer code that has been written. A very brief description of the most important modules is given.
In Appendix 1, we give the listings of the subroutines described in (II-3).

The Problem

Let us consider the following problem:

\[
\begin{align*}
\text{Max} & \quad \phi(x) \quad x \in \mathbb{R}^n \\
\text{Subject to:} & \\
(P) & \quad h_\ell(x) \leq 0 \quad \ell = 1, 2, \ldots, m \tag{c-1} \\
& \quad a_j \leq x_j \leq b_j \quad j \in J = 1, \ldots, n \tag{c-2} \\
& \quad x_j \text{ integers} \quad j \in \mathbb{Z} \tag{c-3}
\end{align*}
\]

We assume that:

(i) \( \phi(x) \) and \( h_\ell(x) \) are nonlinear functions, continuously differentiable.

(ii) Constraints (C-1) define a domain which may be convex or non-convex.

(iii) Constraints (C-2) define a parallelootope \( \Pi \).

\( \Pi \) is assumed to be bounded.

(iv) Without loss of generality, we can assume that \( a_j \) and \( b_j \) are integers.
If \( E \neq J \), only some of the variables must be integer. The problem to solve is said to be "mixed integer nonlinear programming" problems. In the following pages, we propose a method to solve problem \((P)\).

I. The Bounded Branch and Bound Method (BBB)

I.1 Brief Outline of the Method

Let \( S = \{ x \in \mathbb{R}^n | x \text{ satisfies (c-1) and (c-2)} \} \)

a) First, we solve the following problem:

\[
(P_0) \begin{cases} 
\text{Max} & \phi(x) \\
\text{s.t.} & X \in S 
\end{cases}
\]

Let \( x^o \) be the optimal solution of \((P_0)\) (if it exists)

b) If \( x^o \) is integer: END

c) Otherwise, \( \exists \ j \in E | x^o \) is not integer. We proceed to the separation of \( S \) into two subsets \( S_1 \) and \( S_2 \) such that:

\[
S_1 = \{ x \in \mathbb{R}^n | x \text{ satisfies (c-1) and (c-2) and } x \in [a, [x^o]] \}
\]

\[
S_2 = \{ x \in \mathbb{R}^n | x \text{ satisfies (c-1) and (c-2) and } x \in ([x^o] + 1, b) \}
\]

([x^o]) means the integer value of \( x^o \). To \( S_1 \), we associate the following problem.

\[
(P_1) \begin{cases} 
\text{Max} & \phi(x) \\
\text{s.t.} & x \in S_1 
\end{cases}
\]
To $S_2$, we associate problem $P_2$:

$$
\begin{align*}
(P_2) \quad \text{Max} \quad & \phi (x) \\
\text{s.t.} \quad & x \in S_2
\end{align*}
$$

Then, we solve one of the problems and put the other one in a list.

d) If all the $(x_i)_{i \in E}$ are integer, go to $e$. Otherwise go to $c$.

e) If this solution is better than the first one, store it. Otherwise, refuse the node.

If there is a problem in the list, solve it and go to $d$. Otherwise: END

I.2 The Oriented Graph Associated with the Problem

Consider a set $A$ such that $A \subseteq E$. Let $x_A = x_j \mid j \in A$ and $\bar{x}_A$ the integer components of $x_A$ satisfying (c-2). To $S=(A, \bar{x}_A)$ we associate the following problem:

$$
\begin{align*}
P(S) \quad \text{Max} \quad & \phi (x) \\
\quad & h_i(x) \leq 0 \quad i \in I \\
\quad & a \leq x_j \leq b \quad j \in J \\
\quad & x_j = \bar{x}_j \quad j \in A
\end{align*}
$$

Let $\hat{x}_S$ and $\hat{\phi}_S$ be the optimal solution of $P(S)$.

a) The couple $S=(A, \bar{x}_A)$ represents a node of the graph $G$.

b) To each node $S$, we associate its "level" in the graph, called $t_S$.

$t_S$ is equal to the number of components of $x$ which are integers.

c) If $A=\emptyset$ (we have only (c-1) and (c-2)), we solve the continuous nonlinear programming problem. The correspondant node $S_0$ is called the "root" of the arborescence.

d) When $E(S) = E$, (where $E(S) = \{j \in E \mid x_j \text{ is integer}\}$) constraint (c-3) is
therefore satisfied. We have found a solution to problem (F).

The corresponding node is called "terminal node".

e) If $S$ is not a "terminal node", let's consider the variable

$\beta \in E - E(S)$ and let us define a successor $T$. The level of $T$ is $t_T = t_S + 1$.

$T$ is defined by the couple $(B, \bar{x})$ where:

$$B = E(S) \cup \beta$$

$$\hat{x} = x \ orall \ j \in E(S)$$

$$j$$

$$\bar{x} = [\bar{x}(S)] \ or \ [\bar{x}] + 1$$

f) In general, if $S = (A, \bar{x})$ is not a terminal node, we consider the nodes $T$ (with level $t_S + 1$) defined by:

$$\beta \in E - E(S)$$

$$T = (B, \hat{x})$$

$$B = E(S) \cup \beta$$

$$\bar{x} = x \ orall \ j \in E(S)$$

$$j$$

$$\bar{x} = [\bar{x}(S) + \gamma]$$

i) If $\gamma = -1, 2, -3, \ldots$, the nodes $T$ are in the left wing of the graph. The origin of the left wing is the node corresponding to $\gamma = -1$

(ii) If $\gamma = 0, 1, 2, \ldots$, the nodes $T$ are in the right wing. Its origin is the node corresponding to $\gamma = 0$.

g) $T$ is called the successor of $S$ if $ST$ is an arc of the arborescence.

$T$ is called the descendant of $S$ if an elementary path exists between $S$ and $T$. 
Different States of the Nodes in the Arborescence

We use the following graphical language:

0 accepted node
x refused node

R1: So is accepted but all its descendants are refused

A2: Node $S_0$ is accepted.

0A2: $T$ is a descendant of $S$. It is accepted. It belongs to the right wing originated from $S$. No nodes of the opposite wing were investigated.

A02: Same as for 0A2 but for a left wing

RA2: The left wing is refused.

AR2: The right wing is refused.

OR3: $S$ is accepted, the right wing is refused, the left wing not yet explored.

RO3: $S$ is accepted, the left wing is refused, the right wing not yet explored.

ORA3: $S$ is accepted. All its descendents are refused. Left wing not yet explored.

AR03: Same as ORA3 but the right wing is not yet explored.
RRA3: S is accepted, its descendants are refused. The left wing is also refused.

ARR3: Same as RRA3 but the right wing is refused.

RR4: S is accepted. Both wings originated from S are refused. S, which has been previously accepted, will now be refused because all its descendants are refused.
I.4 RULES RELATED TO THE GRAPH G

We shall use the following rules in order to use the graph \( G \).

**Rule 0:** If \( t = 0 \), examine the node \( S_0 \). Therefore, we solve problem (P) without constraint (C-3). In order to do so, we use the GRG (4) algorithm since COLVILLE (11) found it faster than the other codes of nonlinear programming. We let \( \hat{\phi} = +\infty \)

**Rule 1:** If the descendants of \( S_0 \) are refused (this case is possible if \( \hat{\phi}_{S_0} > \hat{\phi} \)), END of the exploration. Then two possibilities exist: we have the solution to problem (P) or the constraints (C-1), (C-2) and (C-3) are incompatibles.

**Rule 2:** If at the level \( t \), a node \( S \) is accepted and if its descendants are not refused, examine a successor at the level \( t+1 \).

In this case, two possibilities exist:

(i) accept \( T \) if \( \begin{cases} \hat{\phi}_T = +\infty \\ T \text{ is not a terminal node} \\ \hat{\phi}_T < \hat{\phi} \end{cases} \)

(ii) refuse \( T \)

In all cases, add 1 to the current level.

**Rule 3(i)** If at a level \( t \), we have one of the following possibilities, examine the successor of \( T \) in its wing and accept or refuse it.

**Possibilities**

**ORA3:** \[ T \]

| T is accepted but all its descendants are refused. |

**AR03:** \[ T \]

| T is accepted but all its descendants are refused. |
RRA3: \[\begin{array}{c}
\text{T} \\
\text{x} \\
\text{x}
\end{array}\]  \\
T is accepted but all its descendants are refused and the left wing is also refused.

ARR3: \[\begin{array}{c}
\text{T} \\
\text{x}
\end{array}\]  \\
T is accepted but all its descendants are refused and the right wing is also refused.

(ii) If at the level \(t\), we have one of the following possibilities, examine the origin of the opposite wing and accept or refuse it.

**Possibilities**

OR3: \[\begin{array}{c}
\text{O} \\
\text{T} \\
\text{x}
\end{array}\]  \\
T is accepted, the right wing originated from T is refused, left wing not yet explored.

RO3: \[\begin{array}{c}
\text{x} \\
\text{O} \\
\text{T}
\end{array}\]  \\
T is accepted, the left wing originated from T is refused. The right wing not yet explored.

**Rule 4** When we move up in the arborescence (i.e. when \(t\) diminish), if we have AR03, ORA3 (respectively ARR3, RRA3) and if \(S\) corresponds to an upper bound (respectively to a lower bound) of \((P)\), refuse the wing corresponding to \(S\).

**Rule 5** If we have the following possibility:

\[\begin{array}{c}
\text{O} \\
\text{X} \\
\text{X}
\end{array}\]  \\
two wings refused.

Refuse all the successors originated from both wings subtract 1 from current level.
Rule 6  If \( S \) is terminal (i.e. \( x_j(S) \) is integer \( V_j \cap E \)) then \( S \) is refused.

If \( \hat{\phi}_S < \hat{\phi} \), then \( \hat{x} \) becomes the best solution.

If \( \hat{\phi}_S > \hat{\phi} \), then the best solution is the current one.
### I.5 Transformation of the States of the Nodes by the Rules

Using the rules described in (I.4), we obtain the following transformation table:

<table>
<thead>
<tr>
<th>State</th>
<th>The level before</th>
<th>Rule Applied</th>
<th>States after</th>
<th>The level after</th>
</tr>
</thead>
<tbody>
<tr>
<td>$R_1$</td>
<td>0</td>

</tbody>
</table>
I-6. **PASSAGE FROM NODE S TO NODE T**

Let $S$ be an accepted node at the level $t$. The solution of problem $P(S)$ gave us $\hat{x}(S)$ and $\hat{\phi}_S$. Besides we have $t = \text{card } [E(S)]$.

The node $T$, successor of $S$ may be:

(i) at the same level $t$ as $S$. In this case, it may be a successor in the same wing or at the origin of the opposite wing of $S$.

(ii) at the level $t+1$. In this case, $T$ is at the origin of a wing.

The other wing is still unexplored if we move down in the arborescence, or closed if we move up in the arborescence.

In order to solve $P(T)$, we can choose one of the following strategies:

(a) If the integer value to try is $[\hat{x}_B]$.

We solve the following auxiliary problem:

$$
\begin{align*}
\min & \quad x_B \\
\text{s.t.} & \quad h_i(x) \leq 0, \quad i = 1, \ldots, m \\
& \quad a_j \leq x_j \leq l_j, \quad j \in J = \{1, 2, \ldots, n\} \\
& \quad x_j = \bar{x}_j, \quad \forall j \in E(S) \\
& \quad [\hat{x}_B] \leq x_B
\end{align*}
$$
(b) If the integer value to try is \([\hat{x}_p] + 1\)

In this case, we solve the following auxiliary problem:

\[
\begin{align*}
\max & \quad x_p \\
\text{s.t.} & \quad h_i(x) \leq 0 \quad i = 1, \ldots, m \\
& \quad a_j \leq x_j \leq 1_j \quad j \in J = \{1, 2, \ldots, n\} \\
& \quad x_j = \bar{x}_j \quad \forall j \in E(S) \\
& \quad x_p \leq [\hat{x}_p] + 1
\end{align*}
\]

Notes

- \(\hat{x}(S)\) is a feasible point to the problems \(P_i\) and \(P_S\).
- We can solve \(P_i\) and \(P_S\) using the same code (GRG) as the one used to solve \(P(S)\).
- Let \(x^i = \{x^i_1, x^i_2, \ldots, x^i_n\}\) and \(x^S = \{x^S_1, x^S_2, \ldots, x^S_n\}\) be the optimal solutions to \(P_i\) and \(P_S\).
  
  (a) if \(x^i_p > [\hat{x}_p]\) (respectively \(x^S_p < [\hat{x}_p] + 1\)) we can conclude that a solution that has \(x_p = [\hat{x}_p]\) (respectively \([\hat{x}_p] + 1\)) will be infeasible for \(P(T)\). Therefore, we don't have to solve \(P(T)\). We can refuse node \(T\) without solving \(P(T)\).

  (b) if \(x^i_p = [\hat{x}_p]\) (respectively \(x^S_p = [\hat{x}_p] + 1\)) the solution \(x^i\) of \(P_i\) (respectively \(x^S\) of \(P_S\)) is infeasible for \(P(T)\).
I-7. Case where $\phi(x)$ and $h_i(x)$ are convex

Let's assume that the problem is convex and differentiable. These two properties will allow us:

(i) to refuse a node without solving its corresponding problem.
(ii) to interrupt the iterations in the process of optimization.

(A) Refusal of a node without investigation

Let $T$ be an accepted node at the level $t$. Assume that $T$ is in a wing originated by a node $S$ at the level $t-1$. Let's call $U$ the successor of $T$ at this wing (Fig. 1).

\[ t-1 \]
\[ \hspace{1cm} S \]
\[ \hspace{2cm} T \]
\[ \hspace{1cm} \hspace{1cm} \hspace{1cm} U \]

Fig. 1

Let $S = (A, x_A)$

$T = (B, x_\beta) \left( \begin{array}{c}
\beta_1 \\
x_\beta
\end{array} \right)$

where:

$B = A \cup \{\beta\}$ with $\beta \in E-E(S)$

$\hat{x}_j = \check{x}_j = \tilde{x}_j$, $\forall j \in A$

$\hat{x}_\beta = [\hat{x}_\beta(S)] + 1$

$\check{x}_\beta = \tilde{x}_\beta + \varepsilon$ with $\varepsilon = \{+1\}$ for a right wing

$\tilde{x}_\beta = \check{x}_\beta = -1$ for a left wing
Let's write down Kuhn-Tucker conditions for problem \( P(T) \):

\[ \exists \, \lambda_i(T), \mu_k(T) \text{ such that} \]

\[
\lambda_i(T) \geq 0 \quad \text{(4-a)}
\]

\[
\mu_k(T) \geq 0 \text{ if } \hat{x}_k(T) = a_k \quad \text{(4-b)}
\]

\[
\mu_k(T) \geq 0 \text{ if } \hat{x}_k(T) = b_k \quad \text{(4-c)}
\]

\[
\mu_k(T) = 0 \text{ if } a_k < \hat{x}_k(T) < b_k \quad \text{(4-d)}
\]

\[
\frac{\delta \phi}{\delta x_k} + \sum_{i=1}^{m} \lambda_i(T) \left( \frac{\delta h_i}{\delta x_k} \right) = \mu_k(T), \quad k \in \text{J-B} \quad \text{(4-e)}
\]

\[
\sum_{i=1}^{m} \lambda_i(T) h_i(\hat{x}(T)) = 0 \quad \text{(4-f)}
\]

\[
\phi = \phi + \sum_{i=1}^{m} \lambda_i h_i \text{ is convex. Therefore:}
\]

\[
\phi[\hat{x}(U)] \geq \phi[\hat{x}(T)] + [\hat{x}(U) - \hat{x}(T)] \left( \frac{\delta \phi}{\delta x} \right) x = \hat{x}(T)
\]

\[
\phi[\hat{x}(U) + \sum_{i=1}^{m} \lambda_i(T) h_i(\hat{x}(T))] \geq \phi[\hat{x}(T)] + \sum_{i=1}^{m} \lambda_i(T) h_i(\hat{x}(T))
\]

\[
+ \sum_{k \in \text{J-B}} \left[ \sum_{i=1}^{m} \lambda_i(T) \left( \frac{\delta h_i}{\delta x_k} \right) \right] x = \hat{x}(T)
\]

\[
+ \varepsilon \left[ \sum_{i=1}^{m} \lambda_i(T) \left( \frac{\delta h_i}{\delta x_k} \right) \right] x = \hat{x}(T), \quad \text{(4-g)}
\]

Using (1-1) and (4-a), we have:

\[
\sum_{i=1}^{m} \lambda_i(T) h_i(\hat{x}(T)) \leq 0
\]

Using (4-f), we obtain:

\[
\sum_{i=1}^{m} \lambda_i(T) h_i(\hat{x}(T)) = 0
\]
Using (4-b), (4-c), (4-d) and (4-e), we have:

\[ \sum_{K \in J-B} \left[ \frac{\partial \phi}{\partial x_K} + \sum_{i=1}^{m} \lambda_i(T) \frac{\partial h_i}{\partial x_K} \right] [x(U) - x(T)] \geq 0 \]

\[ \Rightarrow [x(U)] \geq \phi[x(T)] + \varepsilon \left[ \frac{\partial \phi}{\partial \beta} + \sum_{i=1}^{M} \lambda_i(T) \frac{\partial h_i}{\partial \beta} \right] x = x(T) \]  (4-h)

Let \( \hat{\phi}_T = \phi[x(T)] + \varepsilon \left[ \frac{\partial \phi}{\partial \beta} + \sum_{i=1}^{M} \lambda_i(T) \frac{\partial h_i}{\partial \beta} \right] x = x(T) \)  (4-i)

and \( \hat{\phi}_U = \phi[x(U)] \)  (4-j)

Therefore, we obtain:

\[ \hat{\phi}_T \leq \hat{\phi}_U \]  (4-k)

Relationship (4-k) allows us to refuse node U without investigation (i.e. without optimizing). Indeed, let \( \hat{\phi} \) be the value of the objective function corresponding to the best integer solution found till the precedent iteration.

If \( \hat{\phi} \leq \hat{\phi}_T \) \( \Rightarrow \hat{\phi} \leq \hat{\phi}_U \)

Therefore, we can refuse node U.

B. Interruption of the Iterations while Optimizing

(i) When solving problem \( P(S) \), at each iteration, the inequalities give us a lower bound of \( \phi_S \).

Let \[ \begin{cases} x^1 & \text{be the current variable at the iteration } 1, \\ \phi & \text{be the best integer solution found.} \\ \phi^1 & \text{be the lower bound associated with } x^1 \end{cases} \]

when \( l \to \infty \), \( \phi^1 \to \hat{\phi}_S \).

If node S must be refused because \( \hat{\phi}_S > \hat{\phi} \), we can stop the iterations of \( P(S) \) when \( \phi > \hat{\phi} \). We can obtain the lower bound using \( \phi^1 \) and
\( \mu_k \) defined in the precedent paragraph.

(ii) When we solve problem \( P_i \) (respectively \( P_s \)), we try to make \( x_\beta \) equal to \( [x_\beta^-] \) (respectively \( [x_\beta] +1 \)).

- in \( P_i \) we minimize \( x_\beta \). If \( x_\beta \) could not be reached, we will know it when the lower bound associated to \( x_\beta \) will be greater than \( [x_\beta^-]+1 \). We therefore add the following rule to our algorithm:

**Rule 3bis:** In moving up in the arborescence, if we are in ORA3 or RRA3 (respectively ARO3 or ARR3), then:

(i) if we have an evaluation \( \hat{\gamma} \) for \( T \), the successor of \( S \) in its wing and

(ii) if \( \hat{\gamma} > \hat{\phi} \)

Refuse the wing corresponding to \( S \).

If, while optimizing, we obtain for the problem \( P_i \) (respectively \( P_s \)) a solution close to \( x_\beta \) (i.e. \( x_\beta^{\pm \epsilon} \)), accept the node and stop the iterations.
I-8. Case where $\phi(x)$ and $h_1(x)$ are non-convex

In this paragraph, we don't assume convexity for functions $\phi(x)$ and $h_1(x)$. In this case, two cases of refusal of a node exist.

**first case:** Refuse any node which does not improve the objective function (i.e. when $\hat{\phi}_S > \hat{\phi}$). Therefore, refuse all its descendants.

**second case:** If a variable, already integer, is at one of its bounds, refuse the successor corresponding to its wing.

Therefore, the rules to use are:

**Rule 0:** If $t=0$, investigate node $S_0$ (i.e., solve the continuous nonlinear programming) and let $\hat{\phi} = + \infty$.

**Rule 1:** If the descendants of $S_0$ are refused, end of the exploration.

**Rule 2:** If at the level $t$, a node $S$ is accepted and, if its descendants are not refused, investigate a successor $T$ at the level $t+1$.

**Rule 3:** At the level $t_m$, examine in both wings, the successor $U$ which has the smallest $|\gamma|$.

Using the "first case refusal" defined above, refuse or accept the descendance of $S$ with a higher level.

Using the "second case refusal", refuse the successor of $S$ in its wing.

If $T$ is the successor of another node in the same wing, refuse the latest node.
Rule 4: Moving up in the arborescence, if we have ARO3, ORA3 (respectively AR3, RRA3) and if S corresponds to an upper bound (respectively to a lower bound), refuse the wing corresponding to S.

Rule 5: If we have RR4, refuse all the successors originated from both wings. Subtract 1 from the current level.

Rule 6: If S is terminal, then it is refused.
If $\hat{\phi}_S < \hat{\phi}$, then $\hat{x}(S)$ becomes the best solution
If $\hat{\phi}_S > \hat{\phi}$, then the best solution is the current one.

Globally, the main difference with the case where $\phi(x)$ and $h_1(x)$ are convex is Rule 3. Besides, note that every refusal is final and every acceptance is temporary.
1.9 Case where the Variables are Boolean

If all the variables are boolean we have only the following possibilities:

- Use Rule 3 and first case refusal
- Use Rule 3 and second case refusal
- Use Rule 3 and second case refusal

We can see that the method is converging whatever \( \phi \) and \( h_1 \) are.

But it is clear that the algorithm is effective if we know how to solve \( P(S) \).

Except for this restriction, all the results proposed precedingly can be applied without any hypothesis on \( \phi \) and the domain defined by \( h_1(x) \).

Assuming that \( \phi \) is twice continuously differentiable ABADIE (5)(7) showed how to solve \( P(S) \).

Function \( \phi \) is made convex by letting

\[
\bar{\phi}(x) = \phi(x) + \frac{1}{2} \alpha \sum_{j \in J} x_j (x_j - 1)
\]

where \( \alpha \) is a constant.

Let \( H(x) \) and \( \tilde{H}(x) \) be the matrix of the second derivatives of \( \phi \) and \( \bar{\phi} \).

We have:

\[
\tilde{H}(x) = H(x) + \alpha I
\]

If \( \lambda \) and \( \tilde{\lambda} \) are the smallest eigenvalue of the matrices \( H(x) \) and \( \tilde{H}(x) \)
we obtain the following relationship:

\[
\tilde{\lambda} = \lambda + a
\]

We therefore will have \( \tilde{\lambda} \geq 0 \) for a big value of \( a \). For this value of \( a \), the function \( \phi \) will be convex on the unit cube. By applying the same process to \( h_i(x) \), we can obtain function \( \tilde{h}_i(x) \) convex.

**THEOREM**

Using the precedent fact, for a problem \( P \) which is twice continuously differentiable and totally bivalent, there exist a problem \( \tilde{P} \) such that the sub-jacent continuous problem is convex.

The latest theorem is in fact a generalization of HAMMER-RUBIN's (14) method for the case where \( \phi \) is a function of the second degree and constraints are linear.
1.10 SCHEDULING OF THE FORTUITOUS INTEGER VARIABLES

By solving \( P(S) \), we obtain the optimal solution \( (\hat{x}(S), \hat{\phi}_S) \).

Let \( E(S) = \{ j \in E | \hat{x}_j(S) \text{ is integer} \} \)

We have \( \Delta \subset E(S) = E \).

If \( E(S) \neq \emptyset \), we can say that by solving \( P(S) \), we obtained one or more "fortuitous integer variables".

By obtaining \( \hat{x}(S) \) and \( \hat{\phi}_S \) we have \( \hat{x}_j = x_j \), \( \forall j \in A \). If by solving \( P(S) \) we have made appear \( j \in E \setminus A \) such that:

\[
\hat{x}_{j_1} = a_{j_1}
\]

or

\[
\hat{x}_{j_1} = b_{j_1}
\]

The variable \( x_{j_1} \) is called "fortuitous integer variable". Let

\[
E_f = j_1, j_2, \ldots, j_f
\]

be set of the index of \( E \) corresponding to fortuitous integer variables in the solution \( x(S) \). We have:

\[
E(S) \subset E
\]

and

\[
E(S) = E_f \subset A
\]

If, while investigating the node \( S \), the level was \( t \), it becomes \( t + f \) after the analysis of \( x(S) \). The search for the fortuitous integer variables is made on the variables which are not integer at the level \( t \). The order of discovering these variables is dependent on the order in which will be ranked the variables which are not yet integer. In order to eliminate many nodes from the arborescence, it will be interesting to have at the highest levels, the fortuitous integer variables which in its descendence there is a probability to
find a good integer solution. Therefore, we will have to change the scheduling of those fortuitous integer variables.

CRITERION USED TO MODIFY THE SCHEDULING OF THE FORTUITOUS INTEGER VARIABLES (FIV)

We have indicated that the FIV are variables at their bounds. They are therefore non-basic variables. In such a case, the components corresponding to the reduced gradient are zero. Therefore, we can use the following criterion:

"RANK THE FIV in the decreasing order of their reduced gradient components". If the absolute value of a component of the reduced gradient is small, a small augmentation of the value of the considered point, will have no effect on the objective function. We can expect that an integer solution found in the descendance of this point will lead to a value of the objective function not too far from the continuous optimal solution.
I.11 Choice of the Separation Variable

Let S be an accepted node at the level t. The solution of \( P(S) \) gives us \( \hat{x}(S) \), \( \hat{\phi}_S \) and \( E(S) \). When we want to investigate a successor T at the level t+1, we have to choose:

(a) an index \( \beta \in E-E(S) \)

(b) the wing originated from S and containing T.

We call \( E-E(S) \) or any subset of \( E-E(S) \), the "choice set".

In linear programming, we can compute for the variables included in the choice set, penalties. Those penalties allow us to choose a separation variable and a wing. In nonlinear programming, those penalties are not applicable. Therefore, we propose other criteria.

**Criterion 1 - choice of the closest variable to an integer**

We first determine the variable \( x_j \) which is the closest to an integer value, say \( e_j \).

(i) if \( e_j = [x_i] \) we solve problem \( R^j_{K+1} \) obtained by adding to \( P_K \) the constraint \( x_j < e_j \).

(ii) if \( e_j = [x_i] + 1 \), we solve problem \( R'_j_{K+1} \) obtained by adding to \( P_K \) the constraint \( x_j > e_j \).

**Criterion 2 - Choice of the Closest Variable to a Half-Integer**

After solving \( P_K \), each variable \( x_j \) is such that:
We choose $x_j$ such that:

$$x_j = \frac{2e_j + 1}{2}$$

(i) if $e = \lfloor x \rfloor$, we solve problem $R_{K+1}^j$ defined above

(ii) if $e = \lfloor x \rfloor + 1$, we solve problem $R_{K+1}^j$ defined above.

**Criterion 3 - Put in a List the Problem Corresponding to the biggest pseudo-cost**

Let $R_K$ be a node of the arborescence, and $R_1$ and $R_m$ its direct successors obtained by adding respectively $x_j < \lfloor x_j \rfloor$ and $x_j \geq \lfloor x_j \rfloor + 1$

Define:

$\phi_K = \text{value of the objective function at node } R_K$

$\phi_m = \text{value of the objective function at node } R_m$

$f_j = \text{the decimal part of } x_j$

We define the lower pseudo-cost relative to $x_j$, the quantity

$$A_{j}^{(K)} = \frac{\phi_K - \phi_1}{f_j}$$

and the upper pseudo-cost relative to $x_j$, the quantity
\[ B_j(K) = \frac{\phi_K - \phi_m}{1-f_j} \]

\( A_j(K) \) is the diminution of the objective function corresponding to a decrease of one unit of \( x_j \).

\( B_j(K) \) is the diminution of the objective function corresponding to an increase of one unit of \( x_j \).

The expression \( \max \{ \max (A_j, B_j) \} \) gives us an index \( i \) and one pseudo-cost (either \( A_i \) or \( B_i \)).

(i) If the maximum is reached for \( A_i \), put in the list the problem obtained by adding to \( R_K \) the constraint \( x_i \leq [x_i] \).

(ii) If the maximum is reached for \( B_i \), we put in the list the problem obtained by adding to \( R_K \) the constraint \( x_i \geq [x_i] \).

In both cases, we solve immediately the problem which was not put in the list.

**Criteria 4 - Put in the list the problem corresponding to the Biggest Diminution of the Objective Function**

This time, we use the expression

\[ \max \{ \max (A_j f_j, B_j (1-f_j)) \} \]
1-13 CONVERGENCE OF THE ALGORITHM

The number of nodes in the graph G is finite. Besides, we never meet twice the same node. Therefore, after a finite number of steps, the algorithm gives us a solution to problem (P). If it is not the case, we can conclude that the constraints (C-1), (C-2) and (C-3) are incompatibles.

1-14 NUMBER OF NODES STORED IN THE MAIN CORE OF THE COMPUTER

Most of the branch and bound methods have a big disadvantage: The number of nodes to be stored is increasing very rapidly (about $2^n$). For large-scale mathematical programming problem, one has to use secondary storage, in order to store all the informations relative to each node. The disadvantage associated with the usage of secondary storage is that the execution time increases very rapidly.

In order not to use secondary storage (and therefore in order to reduce the execution time), one has to limit the number of nodes to be stored in the main memory. A careful look at the different states of the arborescence using the BBB method, indicates that we store at the most an accepted node at each level. Using the fact that we store the root but not the terminal node, the number of nodes stored is equal to N, where N is the number of integer variables of the problem (P). We can therefore expect to solve large-scale integer nonlinear programming problem in a reasonable time.
Note

Abadie, Akoka and Dayan (19)(20) have developed two other arborescent methods (called The Bounded Method" and the" Modified Bounded Method".) These methods were tested on the problems used in II-1. As expected, the BBB method converged more rapidly. (The CPU times were significantly lower for BBB). Besides, the number of nodes of the arborescence for the "Bounded Method" and the "modified bounded method" was significantly bigger than for BBB.
Example

Let's apply BBB to the following problem.

\[(P) \quad \min \phi (X) = (5X_1 - 13)^2 + 15(130X_1 - 100X_2 - 23)^2 + 30(20X_1 + 11X_2 - 20X_3)^2 \]
\[
\begin{align*}
5 & \quad 0 \leq X_j \leq 6, \quad J \in J = \{1, 2, 3\} \\
& \quad X_j \text{ integer, } J \in E = \mathcal{J}
\end{align*}
\] (1)

\(\phi(X)\) is convex and differentiable. The convex space is \(\mathbb{R}^3\). By solving the continuous nonlinear programming problem (i.e. (1) without constraint (2)), we obtain:

\[\hat{X}(\phi) = (2.6; 3.15; 3.75), \quad \phi(\hat{X}(\phi)) = 0. \] The solution of (P) is:

\[\hat{X} = (1; 1; 1), \quad \phi(\hat{X}) = 829\]

In the following pages, we present the results.

**Column 1**: \(T = (B, X_B)\) is the node examined in the arborescence. It corresponds to the number of the iteration.

**Column 2**: Set \(B\). It is obtained by applying one of the five criteria described in (I ). In this case, we urged criterion #2.

**Column 3**, \(4, 5\): The values of \(X_1, X_2, X_3\) for the optimal solution of \(P(T)\). We give only the integer values. The asterisk means that \(X_j\) has been fixed and is integer (i.e. \(j = B\)).
Column 6: \( \hat{\phi} \) = the value of the objective function. The optimal value is underlined. We give only the values that improve the objective function.

Column 7: The state of the arborescence.

Column 8: Value of the level \( t_m \) which is equal to the number of integer variables.

**SOLUTION** \( T = 19 \)

The final graph for the problem is given below.

\( j_1 \) means that the node \( i \) is under investigation; variable \( x_j \) is being fixed at the value \( k \).
II. Numerical Computation

II.1 Introduction

The BBB method and the criteria proposed in chapter I have been programmed in FORTRAN IV. They have been tested on a CDC 6600 using the SCOPE system. 10 problems of small size (between 3 and 10 variables) have been used.

4 Problems are convex. 5 other are non-convex and there is one problem with Boolean variables.

Even though the problems may seem easy, nevertheless, they allow us to see all the difficulties related to the arborescence. The CPU times necessary to solve the problems are very slow. Therefore, we may be able to solve a large-scale problems in a reasonable time. In the following page, we present the results for 9 problems. We use the following notations:

\[ \hat{\phi} = \text{optimal value of the objective function} \]
\[ \text{CP} = \text{CPU time, in seconds} \]
\[ \text{NTE} = \text{total number of evaluations} \]
\[ \text{NTO} = \text{total number of optimizations} \]
\[ \text{NSPA} = \text{number of nodes temporary accepted} \]
\[ \text{NRFT} = \text{number of refusal using } \hat{\varphi} \text{ (see \S 7-B)} \]

II.3 Rank of the Criteria

Let's describe two methods of ranking the criteria. The first method, due to COLVILLE use the mean and the variance of the time necessary to solve problem i by method j. The second method, due to ABADIE, use the best time obtained for the problem.

II.1.1 COLVILLE'S METHOD

Let $t_{ij}$ be the time necessary to solve problem i using criterion j. Define $\overline{t}_{ij} = \text{mean of } t_{ij}$

$\sigma_{t_{ij}} = \text{standard error of } t_{ij}$

For each criterion and for each problem, we compute the following quantity:

$$q_{ij} = \frac{-t_{ij} + \overline{t}_{ij}}{\sigma_{t_{ij}}}$$

If $n$ is equal to the number of problems solved using criterion j, the ranking of the criterion j is given by:

$$Q_j = \frac{1}{\sqrt{n}} \sum_{i=1}^{n} q_{ij}$$

II.1.2 ABADIE'S METHOD

Let $t_{ij}$ be the time necessary for criterion j to solve problem i.

Let $\min_j (t_{ij})$ be the best time obtained for problem i.

We compute the following quantity:

$$h_{ij} = \frac{t_{ij}}{\min_j (t_{ij})}$$
If \( n \) represents the number of problems solved, we obtain a rank for the criterion \( j \) using the following formula:

\[
H_i = \frac{1}{n} \sum_{i=1}^{n} \frac{t_{ij}}{\min_j (t_{ij})}
\]
\[ \sum_{i=1}^{n} \frac{1}{i^2} = \frac{\pi^2}{6} \]
If we apply both methods to Table 1 representing the CPU times necessary to solve each problem using the five criteria, we obtain a ranking for each criteria. The values for each criterion is given in Table 2.

**TABLE 3**

The best criterion is 4 (i.e. put in the list the problem corresponding to \( \max \left( A_j f_j, B_j (1-f_j) \right) \))
As an indication, we give below another method to order the criteria. Let \( x_{ij} \) be the total number of optimizations needed by criteria \( j \) to solve problem \( i \). Let \( \min(x_{ij}) \) be the smallest number of optimizations for problem \( i \). The following quantity gives us an order for each criteria:

\[
M_i = \frac{1}{n} \sum_{i=1}^{n} \frac{x_{ij}}{\min(x_{ij})}
\]

We feel that this quantity is useful when one has to do with linear programming.
II.3 Presentation of the Computer Code

The flowchart of the code is:
Let us now detail each block of the flowchart.

A. The Main Program

In the main program, the user has to initialize the problem. The user indicates the following parameters

- number of variables
- upper bound and lower bound for each variable
- number of equalities in the constraints
- number of inequalities in the constraints
- characteristic of the problem (convex or non-convex)

B. Subroutine Fecon

In this subroutine, the user has to give the objective function.

C. Subroutine Contr

The user has to specify in this subroutine, the set of constraints.

D. Subroutine Gradf

The user must indicate in this subroutine, the gradient of the objective function:

\[ DfI (I) = \frac{\partial \phi}{\partial X(I)} \]

E. Subroutine Jacob2

The user must indicate the Jacobian of the constraints

\[ C(I,J) = \frac{\partial VC(x)}{\partial x_j} \]
F. **Subroutine BBB**

This subroutine is described in details in Chapter 3. BBB calls OPTIM which leads to the solution of the continuous nonlinear programming problem. It calls also CHOIX and ARBITR in order to use the five criteria defined in (II.1).

G. **Subroutine Optim**

Called by BBB, optim considers the variables not yet integer and solve the continuous nonlinear programming problem using GRG. It searches the fortuitous integer variables (see I.10).

H. **Subrouting Choix**

This subroutine allows to choose the "separation variable".

(see I.11).

It uses the five criteria defined in (I-11).

I. **Subroutine Arbitr**

It allows us to determine whether the optimization by GRG leads to an optimal solution.

J. **Subroutine GRG**

It is the code used by ABADIE and ranked first by COLVILLE.

It allows to solve continuous nonlinear programming problems (4).
