Abstract

Most biological nitrogen fixation is catalyzed by molybdenum-dependent nitrogenase, an enzyme complex comprising two component proteins that contain three different metalloclusters. Diazotrophs contain a common core of nitrogen fixation *nif* genes that encode the structural subunits of the enzyme and components required to synthesize the metalloclusters. However, the complement of *nif* genes required to enable diazotrophic growth varies significantly amongst nitrogen fixing bacteria and archaea. In this study, we identified a minimal *nif* gene cluster consisting of nine *nif* genes in the genome of *Paenibacillus* sp. WLY78, a gram-positive, facultative anaerobe isolated from the rhizosphere of bamboo. We demonstrate that the *nif* genes in this organism are organized as an operon comprising *nifB*, *nifH*, *nifD*, *nifK*, *nifE*, *nifN*, *hesA* and *nifV* and that the *nif* cluster is under the control of a σ^70^ (σ^ɛ^)-dependent promoter located upstream of *nifB*. To investigate genetic requirements for diazotrophy, we transferred the *Paenibacillus* *nif* cluster to *Escherichia coli*. The minimal *nif* gene cluster enables synthesis of catalytically active nitrogenase in this host, when expressed either from the native *nifB* promoter or from the T7 promoter. Deletion analysis indicates that in addition to the core *nif* genes, *hesA* plays an important role in nitrogen fixation and is responsive to the availability of molybdenum. Whereas *nif* transcription in *Paenibacillus* is regulated in response to nitrogen availability and by the external oxygen concentration, transcription from the *nifB* promoter is constitutive in *E. coli*, indicating that negative regulation of *nif* transcription is bypassed in the heterologous host. This study demonstrates the potential for engineering nitrogen fixation in a non-nitrogen fixing organism with a minimal set of nine *nif* genes.

Introduction

Although fixed nitrogen plays a critical role in the global food supply, overuse of chemical nitrogen fertilizers has led to increased costs for farmers and harmful consequences for the environment and human health. Biological nitrogen fixation, the conversion of atmospheric N\(_2\) to NH\(_3\) offers a natural means of providing nitrogen for plants [1]. There has been a long-standing interest in reducing dependence on fertilizers through engineering non-legume crops that ‘fix’ nitrogen but maintain growth yields [2], [3]. Achieving this goal will require elucidating the minimal number of genes required to sustain biological nitrogen fixation.

Most biological nitrogen fixation is catalyzed by molybdenum-dependent nitrogenase, which is distributed within bacteria and archaea. This enzyme is composed of two component proteins, MoFe protein and Fe protein. The MoFe protein component is an \(_2\)Fe\(_3\)S\(_2\) heterotetramer (encoded by *nifD* and *nifK*) that contains two metalloclusters; FeMo-co, a [Mo-7Fe-9S-C-homocitrate] cluster which serves as the active site of substrate binding and reduction and the P-cluster, a [8Fe-7S] cluster that shuttles electrons to FeMo-co. The Fe protein (encoded by *nifH*) is a homodimer bridged by an intersubunit [4Fe-4S] cluster that serves as the obligate electron donor to the MoFe protein. The assembly pathway for the biosynthesis of nitrogenase is complex. Apart from the structural subunits encoded by *nifH*, *nifD* and *nifK*, several genes are required for the biosynthesis of the metalloclusters, in addition to other gene products necessary to produce a fully functional enzyme. It is now well established from genetic and biochemical analysis that *nifE*, *nifN*, *nifX*, *nifQ*, *nifY*, *nifJ* and *nifH* contribute to the synthesis and insertion of FeMo-co into nitrogenase, that *nifU*, *nifS* and *nifZ* play an important role in synthesis of metalloclusters and that *nifM* is required for proper folder of nitrogenase Fe protein [4]–[7].

The inventory of genes required for diazotrophy varies greatly amongst species, dependent upon the environmental niche and physiology of the host. For example, in *Klebsiella oxytoca*, twenty *nif*
Author Summary

Biological nitrogen fixation plays an essential role in the nitrogen cycle, sustaining agricultural productivity by providing a source of fixed nitrogen for plants and ultimately animals. The enzyme nitrogenase that catalyzes the reduction of atmospheric dinitrogen to ammonia contains one of the most complex heterometal cofactors found in biology. Biosynthesis of nitrogenase and provision of support for its activity requires a large number of nitrogen fixation (nif) genes, which vary according to the physiological lifestyle of the host organism. In this study, we identified a nif cluster with reduced genetic complexity, consisting of nine genes organized as a single operon in the genome of *Paenibacillus* sp. WLY78. When transferred to *Escherichia coli*, the *Paenibacillus* nif cluster enables synthesis of catalytically active nitrogenase, which is competent to reduce both acetylene and dinitrogen as substrates of the enzyme. Environmental regulation of nif gene expression in *Paenibacillus*, in response to either oxygen or fixed nitrogen, is circumvented when the nif operon is expressed from its native promoter in *E. coli*, suggesting that nif transcription in *Paenibacillus* is negatively regulated in response to these effectors.

Results

Genome sequencing of Paenibacillus sp. WLY78 identifies a minimal nitrogen fixation (nif) gene cluster

Paenibacillus sp. WLY78 is a gram-positive, facultative anaerobic, endospore-forming bacterium isolated from the rhizosphere of bamboo [14]. This bacterium has potential use in agriculture, since it is able to fix nitrogen and also produces antimicrobial substances. We therefore determined the genome sequence of bamboo [14]. This bacterium has potential use in agriculture, endospore-forming bacterium is olated from the rhizosphere of Paenibacillus. Primers used and amplified products (numbered) are given below the schematic representation of the genes. (B) Result of RT-PCR reactions with RNA from Paenibacillus sp. WLY78 shown under N₂-fixing conditions. The numbering on the top of the gels corresponds to the product numbers drawn schematically in the outline given above. RT, standard RT-PCR reaction; (−), negative control in which no reverse transcriptase was added to the RT reaction; (+), positive control in which genomic DNA was used as template in the RT-PCR.

Characterization of the Paenibacillus sp. WLY78 nif promoter and transcription unit

The transcriptional start site (TSS) of the nif gene cluster in Paenibacillus sp. WLY78 was determined by using the 5'-RACE (Rapid Amplification of cDNA Ends) method. The TSS was located 59 bp upstream of the translational start site of nifB and a putative promoter was identified 6 nucleotides preceding the TSS (Figure 3). The −33 (TTGACT) and −10 (TAAGAT) sequences in the nifB promoter were similar to the corresponding consensus sequences (TTGACA and TATAAT respectively) of E. coli σ⁷₀-dependent promoters. Unlike other members of the Bacillales, the Paenibacillus sp. WLY78 genome does not contain a homolog of rpoN and consequently σ²⁴-dependent −24/−12 promoter sequences were not observed either upstream of the nif cluster or in the 5’ regions of other genes in the Paenibacillus sp. WLY78 genome (data not shown). Downstream of nifV, a potential transcriptional termination site was identified, containing two potential stem loops followed by a T-rich region (Figure 3B). These findings indicate that the nif genes in Paenibacillus sp. WLY78 are organized as a single operon containing 9 genes, which is transcribed from an rpoD-dependent promoter.

To analyze the σ⁷₀-dependency of the nifB promoter, electrophoretic mobility shift assays (EMSA) were carried out using either E. coli σ⁷₀-RNAP (RNA polymerase) or σ²⁴ from Paenibacillus sp. WLY78, which was overexpressed and purified from E. coli (Figure 3C). EMSA experiments revealed that both purified σ⁷₀ from Paenibacillus sp. WLY78 and E. coli σ²⁴-RNAP holoenzyme bind to the 50 bp nifB promoter fragment. Competition experiments with non-labelled nifB DNA indicated that the E. coli RNAP holoenzyme binds more tightly to this DNA fragment, since higher concentrations of competitor were apparently required to dissociate the E. coli σ⁷₀-RNAP (Figure 3, panels D and E). EMSA experiments with a scrambled double-stranded oligonucleotide did not reveal binding of either protein (data not shown). These results are consistent with the ability of σ⁴ (σ⁷₀) of Bacillus subtilis to bind to promoters independent of core RNAP [20,21].

To further examine the specificity of binding of E. coli σ⁷₀-RNAP to the Paenibacillus sp. WLY78 nifB promoter, we made substitutions in the −35 (TTGACT to GCTACT) and −10 (TAAGAT to GCAGAC) regions of the promoter (Figure 4A). Binding of E. coli σ⁷₀-RNAP to the nifB promoter fragment was weakened considerably by the presence of the −35 and −10

doi:10.1371/journal.pgen.1003865.g002
substitutions (compare Figure 4, panels B and C), suggesting that *E. coli*ς70-RNAP specifically interacts with the *nifB* promoter from *Paenibacillus* sp. WLY78. In order to confirm this, we performed DNAse I footprinting with a fluorescently labeled 319 bp DNA target carrying the *nifB* promoter and analyzed the digested DNA fragments using a capillary sequencer. As expected, the region protected from DNAse I digestion corresponded to the *nifB* promoter, confirming that *E. coli*ς70-RNAP specifically binds to the 235 and 210 regions upstream of the transcription start site. (Figure 4D). Our studies thus demonstrate that the *nifB* promoter of *Paenibacillus* sp. WLY78 is ς70-dependent and thus distinct from the typical ς54-dependent 224/212 promoters found upstream of *nif* genes in gram-negative diazotrophs.

To verify if the *nifB* promoter of *Paenibacillus* sp. WLY78 is functional in *E. coli*, it was fused to the *lacZ* reporter gene. The level of β-galactosidase activity expressed from the *PnifB::lacZ* fusion in *E. coli* strain JM109 was not influenced either by the concentration of fixed nitrogen in the culture medium or by the external oxygen concentration (Figure 5). Hence, the *Paenibacillus* sp. WLY78 *nifB* promoter is apparently recognized by *E. coli* ς70 RNA polymerase in vivo. These data concur with previous studies where promoters of gram-positive bacteria, for example, *Bacillus steroetherophilus* [22] and *Corynebacterium glutamicum* [23], were shown to be functional in *E. coli*.

The *Paenibacillus nif* gene cluster enables nitrogen fixation by *E. coli*  
To transfer the *Paenibacillus nif* gene cluster to *E. coli*, we cloned a 10.5-kb DNA fragment (containing the sequence from the ATG start codon of *nifB* to the TAA stop codon of *nifV*) in the expression vector pET-28b bringing the *nif* genes under control of the T7 promoter. This construct was then transformed into *E. coli* BL21 (DE3), yielding the engineered *E. coli* strain 78-32. We further cloned the 11-kb full-length *nif* cluster containing its own *nif* promoter and the contiguous nine genes *nifBHDKENXhesAnifV* into the multicopy plasmid pHY300PLK and transformed this into *E. coli* JM109, yielding the engineered *E. coli* strain 78-7 (Figure 6A).

To determine whether the *Paenibacillus nif* cluster functions in *E. coli*, we employed two independent methods to assess nitrogenase activity; firstly, reduction of the alternative substrate acetylene to ethylene, which can be readily quantified by gas chromatography [24], [25] and secondly, a 15N2 enrichment assay to directly measure the incorporation of this tracer into organic nitrogen [26]. When grown anaerobically in nitrogen-deficient medium, *Paenibacillus* sp. WLY78 Minimal *nif* Gene Cluster
bacillus sp. WLY78 exhibits both acetylene reduction and \(^{15}\text{N}_2\) incorporation (Figure 6, panels B and C). The engineered \textit{E. coli} strain 78-7, which expresses the \textit{nif} genes from the native promoter showed approximately 10% of the specific activity for acetylene reduction when compared with \textit{Paenibacillus} and was competent to assimilate \(^{15}\text{N}_2\). In contrast, when expressed from the T7 promoter and induced with 2 mM IPTG the \textit{Paenibacillus} \textit{nif} cluster exhibited relatively low levels of nitrogenase activity in the recombinant \textit{E. coli} strain 78-32 (Figure 6). Therefore, the engineered \textit{E. coli} strain 78-7 was used for most of the studies reported here. When compared with the recipient \textit{E. coli} strain JM109, the engineered strain 78-7 had an identical cellular phenotype when analyzed by Biolog phenotypic microarrays [27] (data not shown). In comparison with the \textit{Paenibacillus} sp. WLY78 strain, which is capable of diazotrophic growth, the engineered \textit{E. coli} strain 78-7 grew poorly in liquid media with dinitrogen as the sole nitrogen source (data not shown). Therefore, although the recombinant strain expresses active nitrogenase and assimilates \(^{15}\text{N}_2\), this does not enable the engineered \textit{E. coli} strain to grow as a diazotroph.

Minimal \textit{Paenibacillus} \textit{nif} genes required for nitrogenase activity

To further determine the minimal \textit{nif} genes required for nitrogen fixation, we constructed a series of \textit{nif} gene deletions (Figure 6). Neither acetylene nor \(^{15}\text{N}_2\) incorporation was detectable in the \textit{nifB} deletion, supporting the original observation that \textit{nifB} is essential for synthesis of nitrogenase [5]. When \textit{nifV} was deleted, \(^{15}\text{N}_2\) assimilation decreased more significantly than acetylene reduction, in agreement with the substrate reduction properties of \textit{nifV} mutants [28], which are unable to synthesize the homocitrate moiety of FeMo-co [29]. Deletion of \textit{hesA} also influenced \(^{15}\text{N}_2\) incorporation more significantly than acetylene reduction, suggesting that \textit{hesA} is required for nitrogen fixation. In contrast, deleting \textit{nifX} gave rise to a similar decrease (~50%) in the reduction of both substrates. In the \textit{ΔnfxhesA} double deletion, nitrogenase activity was similar to that in the single \textit{hesA} mutant, whereas in the double \textit{ΔhesAnfx} deletion, activities were similar to those exhibited by the single \textit{nfx} mutant. Deletion of three \textit{(nfxhesAnfx}) or four genes \textit{(nfxNxesAnfx}) ablated nitrogenase activity. In all cases the phenotypic defects exhibited by the deletions could be reversed by complementation with plasmids bearing the missing genes (data not shown). These results suggest

Error bars indicate the standard deviation observed from at least two independent experiments.

doi:10.1371/journal.pgen.1003865.g005
that all nine *Paenibacillus* genes (nifBHDKENXhesAnifV) are necessary for optimal nitrogenase activity in *E. coli*.

Effects of fixed nitrogen and oxygen on nif transcription

In many diazotrophs such as *K. oxytoca* and *A. vinelandii*, expression of the *nif* genes is tightly controlled at the translational level in response to the concentration of fixed nitrogen and the oxygen [30]. In addition, the activity of nitrogenase itself can be regulated at the post-translational level in response to environmental effectors [31]. To examine whether the *Paenibacillus* *nif* cluster is subject to similar regulation, we compared the effects of NH$_4^+$ and O$_2$ on in vivo nitrogenase activity and *nif* gene transcription in the native *Paenibacillus* sp. WLY78 strain with that of engineered *E. coli* 78-7 (Figure 7). Both *Paenibacillus* sp. WLY78 and the engineered *E. coli* 78-7 strain did not exhibit nitrogenase activity at O$_2$ concentrations above 5% (Figure 7A). In addition, acetylene reduction by *Paenibacillus* sp. WLY78 was not observed at NH$_4^+$ concentrations above 1 mM. In contrast, the engineered *E. coli* strain 78-7 exhibited nitrogenase activity even in the presence of 200 mM NH$_4$Cl (Figure 7B). The latter observation suggests that the *Paenibacillus* *nif* cluster is not subject to regulation by fixed nitrogen in *E. coli*. In agreement with the acetylene reduction data, the $\alpha$ and $\beta$ subunits of the MoFe protein and the Fe protein component of nitrogenase were only detectable by Western blotting in *Paenibacillus* sp. WLY78 grown under nitrogen fixation conditions, whereas nitrogenase components were detectable in the engineered *E. coli* strain even in the presence of oxygen (Figure S1).

The influence of oxygen and fixed nitrogen on transcription was assessed by RT-PCR using *nifH* and *nifK* probes. Convergent with the acetylene reduction data, *nif* transcription in *Paenibacillus* sp. WLY78 was inhibited by NH$_4^+$ concentrations above 1 mM and by the presence of 21% oxygen (Figure 7C). In contrast, *nifH* and *nifK* transcription in *E. coli* 78-7 was insensitive to the presence of oxygen and fixed nitrogen (Figure 7D). Thus the *Paenibacillus* *nif* genes are constitutively transcribed in the engineered strain indicating that the transcriptional regulation observed in the native host does not occur in *E. coli*.
Figure 7. Effects of O2 and NH4+ on nitrogenase activity and nif gene transcription. (A) and (B) Comparison of the acetylene reduction activities of Paenibacillus sp. WLY78 (panel A) and the engineered E. coli 78-7 strain (panel B), when cultures are grown in the presence of either oxygen or ammonium (at the initial concentrations shown on the y axis). Error bars indicate the standard deviation observed from at least two independent experiments. (C) and (D) Comparison of transcription of nifH and nifK as determined by RT-PCR in Paenibacillus sp. WLY78 (panel C) and E. coli 78-7 (panel D). Initial concentrations of ammonium and oxygen are indicated above relevant lanes. Lanes labeled “+” indicate positive controls in which genomic DNA was used as template in the RT-PCR. Lanes labeled “-” indicate negative controls in which no reverse transcriptase was added to the RT-PCR reaction. In each case a parallel RT-PCR reaction was performed to detect the level of 16S rRNA, to provide a loading control (shown beneath relevant lanes).

doi:10.1371/journal.pgen.1003865.g007

Discussion

Although the biochemical properties and structure of molybdenum nitrogenases are remarkably similar when purified from diverse bacteria and archaea, genetic requirements for the synthesis and assembly of the enzyme and maintenance of its activity differ widely amongst diazotrophs [11], [32], [33]. Some of this diversity is undoubtedly determined by the environmental lifestyle of each diazotroph, the need to protect the enzyme from damage by oxygen and the requirement to provide sufficient ATP and reductant to support enzyme activity under different physiological conditions. Although the conserved nature of the structural genes and the assembly pathway for FeMoco biosynthesis dictates the presence of a common core of structural genes and the assembly pathway for FeMoco biosynthesis, we can look for potential absences in the minimal nif gene operon that is present in E. coli, for example the ability to synthesize high levels of nitrogenase proteins under conditions of nitrogen starvation, limit the capacity for diazotrophic growth. Considering the physiological background of E. coli, one of the notable absences in the minimal Paenibacillus nif gene cluster is the presence of nifJ, which provides the electron transport chain to nitrogenase in some diazotrophs [34], [35]. The activity of Paenibacillus nitrogenase is therefore likely to be reductant limited in E. coli in the absence of this electron transport chain. Another notable absence is nifM, which encodes a cis-trans peptidyl prolyl isomerase required for proper folding of nitrogenase Fe protein in diazotrophic proteobacteria [6]. Potentially this function is provided by a counterpart enzyme encoded elsewhere in the genome in other diazotrophs such as Paenibacillus. However, a functional equivalent of nifM is not present in E. coli, since assembly of active K. oxytoca Fe protein in this background requires the presence of both nifH and nifJ [36]. The Paenibacillus NifH sequence contains the seven conserved proline residues identified in other NifH sequences that are considered to be potential substrates for NifM [6]. However, it is possible that other amino acid substitutions in NifH may enable assembly of Fe protein in the absence of NifM. The Paenibacillus sp. WLY78 nif gene operon does not contain homologs of the nitrogen fixation-specific iron-sulphur cluster assembly pathway encoded by nifU and nifS. As in not enable diazotrophic growth. This implies that this level of enzyme activity is insufficient to support growth on dinitrogen as sole nitrogen source. However, we cannot rule out the possibility that other physiological factors in E. coli, for example the ability to synthesis high levels of nitrogenase proteins under conditions of nitrogen starvation, limit the capacity for diazotrophic growth.
the case of other diazotrophs, this function may be provided by the Suf system, encoded elsewhere in the *Paenibacillus* genome. When *nifH* and *nifM* are expressed in *E. coli*, assembly of the 4Fe-4S cluster in the *E. coli* Fe protein does not require *nifU* and *nifS* [36], [37]. This function is probably provided by the general Isc, Csd or Suf machineries for iron-sulphur cluster biosynthesis in *E. coli*. However, *E. coli* *nifS* is apparently required for the biosynthesis of the P cluster in the MoFe protein, when Nif polypeptides are expressed in *E. coli* [38]. Although *nifU* and *nifS* also participate in FeMoco biosynthesis [37], the requirement for these genes is not absolute, particularly if *nifB* is strongly expressed [38].

Systematic deletion of genes in the *Paenibacillus* *nif* gene cluster suggests they have functions similar to those of other diazotrophs. As anticipated, *nifB* is essential for nitrogen fixation in *E. coli* and the substrate reduction profile of the nifV deletion is expected for a mutant lacking homocitrate synthase and therefore unable to make the homocitrate moiety of FeMo-co [39]. The co-localisation of *hesA* within the *nif* operon is an interesting feature of *Paenibacillus* and other minimal *nif* clusters such as those of cyanobacteria and Frankia (Figure 1). Our deletion analysis demonstrates that *hesA* is important for nitrogenase activity, but the function of *hesC* in nitrogen fixation has not so far been determined. Well-characterised homologs belonging to the ThiF-MoeB-HesA family engage in an ATP-dependent process that activates the C-terminus of partner ubiquitin-like proteins by forming an acyl adenylate complex that facilitates sulfur transfer [40], [41]. Ubiquitin-like proteins contain a conserved C-terminal Gly-Gly motif that is the target for adenylylation by the activating enzyme [42]. Intriguingly, both NifB and NifN from *Paenibacillus* contain C-terminal Gly-Gly motifs and therefore are potential targets for adenylylation by HesA. Given the potential role of HesA as an activating enzyme for sulphur transfer, it is tempting to speculate that HesA may perform a role in metallocluster biosynthesis.

In the Proteobacteria, *nif* genes are generally transcribed from *σ*74-dependent promoters that are subject to transcriptional activation by the enhancer binding protein NifA and are regulated in response to fixed nitrogen and oxygen [30]. However, much less is known about *nif* gene regulation in other diazotrophs where this paradigm is absent. Our results demonstrate that the *nif* cluster of *Paenibacillus* sp. WLY78 is transcribed from a *σ*73-dependent promoter, most likely as a single operon, and that transcription of the *nif* genes is subject to regulation in response to the extracellular concentration of oxygen and fixed nitrogen in *Paenibacillus*. As no transcriptional regulation by either oxygen or fixed nitrogen was detectable when the *Paenibacillus* sp. WLY78 *nif* cluster was expressed from the native *nifB* promoter in *E. coli*, it seems likely that the transcriptional regulation of the *nif* system in *Paenibacillus* involves repression mechanisms. Potential candidates for repression of transcription in response to the nitrogen source are the global nitrogen regulators GlnR and TnrA, which are present in *Paenibacillus* [43].

In summary our results demonstrate that a minimal *nif* gene cluster derived from a gram-positive bacterium can function to synthesize active nitrogenase when expressed in the very different host environment of *E. coli*. This raises various questions concerning the repertoire of genes required for nitrogen fixation and may have important biotechnological implications for engineering diazotrophic eukaryotes.

**Materials and Methods**

**Strains and media**

*Paenibacillus* sp. WLY78 was isolated from the rhizosphere of bamboo in Beijing, China by enrichment in nitrogen-free medium after heating at 100°C for 10 min [14]. Strain WLY78 is similar to *P. polymyxa* based on 16S rDNA phylogeny and whole genome sequencing. *E. coli* strains JM109 and BL21 were used as the recipient strains for constructing the engineered *E. coli* strains carrying nitrogen fixation genes.

*Paenibacillus* sp. WLY78 and the engineered *E. coli* strains were routinely grown in LB or LD medium (per liter: 2.5 g NaCl, 5 g yeast and 10 g tryptone) at 30°C with shaking. When appropriate, antibiotics were added in the following concentrations: 40 μg/ml chloramphenicol, 100 μg/ml ampicillin, and 20 μg/ml tetracycline for maintenance of plasmids.

Nitrogen-free, nitrogen-deficient and nitrogen-excess media were used in this study. Nitrogen-free medium contained (per liter) 10.4 g Na₂HPO₄, 3.4 g KH₂PO₄, 26 mg CaCl₂·2H₂O, 30 mg MgSO₄·7H₂O, 0.3 mg MnSO₄, 36 mg Ferric citrate, 7.6 mg Na₂MoO₄·2H₂O, 10 μg p-aminobenzoic acid, 5 μg biotin and 4 g glucose as carbon source. Nitrogen-deficient medium contained 2 mM glutamate as nitrogen source in nitrogen-free medium. Nitrogen-excess medium contained 100 mM NH₄Cl in nitrogen-free medium [14].

**Acetylene reduction assays**

For nitrogenase activity assays, *Paenibacillus* sp. WLY78 and the engineered *E. coli* strains were grown in 5 ml of LD media (supplemented with antibiotics) in 50 ml flasks shaken at 250 rpm for 16 h at 30°C. The cultures were collected by centrifugation, washed three times with sterilized water and then resuspended in nitrogen-deficient medium containing 2 mM glutamate as nitrogen source (supplemented with antibiotics for the engineered *E. coli* strains and IPTG when necessary) to a final OD₆₀₀ of 0.2–0.4. Then, 1 ml of the culture was transferred to a 25-ml test tube and the test tube was sealed with rubber stopper. The headspace in the tube was then evacuated and replaced with argon gas [14]. After incubating the cultures for 6–8 h at 30°C with shaking at 250 rpm, C₂H₂ (10% of the headspace volume) was injected into the test tubes. After incubating the cultures for a further 3 h, 100 μl of culture headspace was withdrawn through the rubber stopper with a gas tight syringe and manually injected into a HP6890 gas chromatograph to quantify ethylene production. All treatments were in three replicates and all the experiments were repeated three or more times.

For measuring the effect of ammonium on nitrogenase activity, nitrogen-deficient medium was supplemented with NH₄Cl at the concentrations indicated and the cultures were also grown under anaerobic conditions. For measuring the effect of oxygen on nitrogenase activity, nitrogen-deficient medium containing 2 mM glutamate as nitrogen source was used, and oxygen was adjusted to the initial concentration indicated at the start of the incubation.

**¹⁵N₂ incorporation assay**

*Paenibacillus* sp. WLY78 and the engineered *E. coli* strains were grown overnight in LD medium. The cultures were collected and resuspended in 70 ml nitrogen-deficient medium containing 2 mM glutamate as nitrogen source, to an OD₆₀₀ of 0.4 in a 120 ml serum bottle. The serum bottles were filled with N₂ gas, and then 8 ml gas was removed and 5 ml ¹⁵N₂ (99%, Shanghai Engineering Research Center for Stable Isotope) gas was injected. After 72 h of incubation at 30°C, the cultures were collected, and were freeze dried, ground, weighed and sealed into tin capsules. Isotope ratios are expressed as δ¹⁵N whose values are a linear transform of the isotope ratios ¹⁵N/¹⁴N, representing the per mille difference between the isotope ratios in a sample and in atmospheric N₂ [26].
Genome sequencing, assembly and annotation

Total DNA was extracted from *Paenibacillus* sp. WLY78. DNA sequencing was performed using Illumina technologies. A total length of 600,000,120 base pairs of reads was obtained, to enable the assembly of all tags using SOAP denovo. 1.04 assembler [44]. Finally, 87 scaffolds were assembled, giving 101.3-fold coverage of the genome. Glimmer 3 (version 3.0.2) was used for gene finding [45]. Transfer RNA genes were identified by the program rRNAscan-SE [46]. Genes coding for proteins with known functions were annotated by searches against KEGG Genes, Pfam, and SWISS-PROT. The complete genome sequence of *Paenibacillus* sp. WLY78 has been deposited at DDBJ/EMBL/Genbank under the accession ALJY00000000. The version described in this paper is version ALJY01000000.

Construction of recombinant plasmids and recombinant *E. coli* strains

Genomic DNA of *Paenibacillus* sp. WLY78 was used as template for cloning *nif* genes. Primers used for construction of the engineered *E. coli* strains are listed in Table S2. Recombinant plasmids and strains are listed in Table S3.

Transcription start site identification

The 5′-RACE method was used to determine the transcription start site (TSS) using the SMARTer RACE cDNA Amplification Kit (Clontech). Gene-specific primers are listed in Table S2. The PCR product was cloned into the pMD18-T Vector and then sequenced.

Overexpression and purification of σ70 from *Paenibacillus* sp. WLY78 in *E. coli*

A 1134 bp DNA fragment carrying the *spaD* gene (encoding σ70 of *Paenibacillus* sp. WLY78) was PCR amplified with primers sigma A-F and sigma A-R (Table S2). The PCR product was ligated to the pET-28b expression vector, yielding plasmid pET28-σ70. *E. coli* strain BL21 (DE3) was transformed with expression plasmid pFootdown (Table S2). The 5′-FAM-labeled DNA fragment (400 ng) was incubated with the *E. coli* σ70-RNAP (10 pmol) for 30 min at 25°C. Bovine serum albumin (BSA) was used for the control experiment. After incubation, the mixtures were digested with DNase I for 40 seconds at 37°C and then the reactions were stopped by adding 0.2 M EDTA (pH 8.0). The digested DNA fragments were extracted with phenol-chloroform, precipitated with ethanol, and the pellets dissolved in Mini-Q water. The samples were sequenced with the ABI 3730 DNA analyzer by Genolab Co. and the data were analyzed with GeneMarker software.

Construction of a nifB promoter: lacZ fusion

A 100 bp DNA fragment (Pnif (from −97 to +3 relative to the nifB transcription start codon) containing the nifB promoter was amplified from total DNA of *Paenibacillus* sp. WLY78 using primers (Table S2). The fragment was cloned into the promoterless plasmid pPR9TT, yielding plasmid pPR9TT-Pnif. The plasmid was then transformed into *E. coli* JM109, yielding *E. coli/ PnifB::lacZ*.

For β-galactosidase activity assays, *E. coli* JM109/pPR9TT and *E. coli/PnifB::lacZ* were grown overnight in LB medium at 30°C with shaking. The cultures were collected by centrifugation, washed three times with sterilized water and then resuspended in nitrogen-deficient medium containing 2 mM glutamate as nitrogen source to a final OD600 of 0.2–0.4. For measuring the effect of oxygen on nitrogenase activity, the test tubes were capped and filled with argon, and the oxygen concentration was adjusted to the initial concentration indicated and cultures were then incubated for 20 h at 30°C with shaking.

β-galactosidase activity was assayed according to the method described by Miller [48]. A 100 μl sample was taken and then mixed with 900 μl Z buffer containing β-mercaptoethanol, 40 μl chloroform and 20 μl 10% SDS and then shaken for 20 sec. Then 200 μl o-nitrophenyl-β-D-galactopyranoside (ONPG) (4 mg/ml) was added to the mixture and incubated in a water bath for 20 min at 37°C. The reaction was stopped with 500 μl 1M Na2CO3 solution. The mixture was then centrifuged for 15 min at 12000 rpm and the supernatant was used to measure the OD420 and OD550 values. 1 unit of β-galactosidase activity = [1000×(OD420–1.7 OD550)]/[Time (min)×vol (ml)×OD600].

RT-PCR

For RT-PCR, *Paenibacillus* sp. WLY78 and the recombinant *E. coli* strains were grown in N2-fixing conditions (without NH4Cl and...
O₂, non-N₂-fixing conditions (100 mM NH₄Cl and 21% O₂) or at different concentrations of NH₄Cl in the absence of O₂ or at different concentration of O₂ in the absence of NH₄Cl. The cultures were harvested by centrifugation at 4 °C, and total RNA was isolated using the PrimeScript RT reagent Kit with gDNA Eraser (Takara Bio) according to the manufacturer’s instructions. The possibility of contamination of genomic DNA was eliminated by digestion with RNase-free DNase I (Takara Bio). The integrity and size distribution of the RNA was verified by agarose gel electrophoresis, and the concentration was determined spectrophotometrically. Synthesis of cDNA was carried out using RT-Prime Mix according to the manufacturer’s specifications (Takara Bio). 0.8 μg of cDNA was used for RT-PCR. The nifH and nifK transcripts were detected by using an RT-PCR Kit with 16S rDNA as a control. Primers for nifH, nifK and 16S rDNA used for PCR are listed in Table S2.

**Western blot assays for NifH and NifDK expression**

For Western blotting, cultures of *Paenibacillus* sp. WLY78 and the engineered *E. coli* strains were grown either in non-N₂-fixing conditions (LD medium and 21% O₂) and harvested after 6–8 h of incubation or grown in N₂-fixing conditions (2 mM glutamate and without O₂) and harvested after 20 h of incubation, respectively. The cell pellet collected from 4 ml cultures at OD₆₀₀ = 1 was dissolved in 200 μl sodium dodecyl sulfate (SDS) gel-loading buffer, boiled for 5 min and then 20 μl was loaded onto the stacking gel. Proteins were separated by sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) with an acrylamide:bis-acrylamide ratio of 17:2.1. Anisera raised against MoFe protein and Fe protein of *K. oxytoca* M5aI were used as probes for Western blotting. The MoFe protein and Fe protein components of nitrogenase were purified from *K. oxytoca* M5aI under anaerobic conditions and then used to make rabbit antisem.

**Supporting Information**

**Figure S1** Immunological detection of nitrogenase MoFe protein and Fe protein in *Paenibacillus* sp. WLY78, the engineered *E. coli* strain 78-7 and nif gene deletion mutants. (A) Cultures grown in N₂-fixing conditions (2 mM glutamate and in the absence of O₂). (B) Cultures grown under non-N₂-fixing conditions (LD medium and 21% O₂). Antisera against *K. oxytoca* MoFe and Fe proteins, respectively, were used as probes. WT indicates *Paenibacillus* sp. WLY78. Vector indicates *E. coli* JM109 carrying empty vector pHY300PLK.

**Table S1** Identity of *Paenibacillus* sp. WLY78 Nif polypeptides to those of other diazotrophs.

**Table S2** Primers used in this study.

**Table S3** Bacterial strains and plasmids used in this study.
