ABSTRACT

The influence of finite radial geometry on the longitudinal wiggler free electron laser instability is investigated for TE mode perturbations about a uniform density electron beam with radius \( \hat{R}_b \). The equilibrium and stability analysis is carried out for a thin, tenuous electron beam propagating down the axis of a multiple-mirror (undulator) magnetic field \( B_0(\chi) = B_0(1 + (\delta B/B_0) \sin \chi) \hat{x} \), where \( \lambda_0 = 2\pi/k_0 = \text{const.} \) is the wiggler wavelength. It is assumed that \( k_0^2 R^2 < 1 \), and that perturbations are about the self-consistent Vlasov equilibrium \( f_b^0(\chi, \rho) = (\hat{n}_b/\pi)^2 \delta(\rho - 2\gamma_b m_b v_b - 2\gamma_b m_b \hat{T}_b) \times \delta(\rho - \gamma_b m_b v_b) \), where \( \rho = p^2 + \hat{p}_\theta^2 \), \( \hat{p}_\theta \) is the canonical angular momentum, and \( \hat{n}_b \), \( \gamma_b \), \( m_b \), \( \hat{T}_b \) and \( V_b \) are positive constants. For \( \delta B/B_0 < 1 \) and slow beam rotation \( (\omega_b < \omega_{cb} = eB_0/\gamma_b m_c) \), the equilibrium density is uniform \( (\hat{n}_b) \) out to the beam radius \( \hat{R}_b = (2T_b/\gamma_b m_b v_b)^{1/2} \). Detailed free electron laser stability properties are investigated for the case where the amplifying radiation field has TE-mode polarization with perturbed field components \( (\delta E_x, \delta B_r, \delta B_z) \). The matrix dispersion equation is analyzed in the diagonal approximation, and it is shown that the positioning of the beam radius \( (\hat{R}_b) \) relative to the conducting wall radius \( (R_c) \) can have a large influence on the growth rate and detailed stability properties. Analytic and numerical studies show that the growth rate increases as \( \hat{R}_b/R_c \) is increased.

I. INTRODUCTION AND SUMMARY

There have been several theoretical\(^1\)\(^{-26}\) and experimental\(^{27\text{-}35}\) investigations of coherent radiation generation by free electron lasers that use an intense relativistic electron beam as an energy source. Both longitudinal\(^1\)\(^{-5}\) and transverse\(^6\)\(^{-18}\) wiggler magnetic field geometries have been considered, and there have been many theoretical estimates of the gain (growth rate) that treat the system as infinite and uniform transverse to the beam propagation direction. Few calculations,\(^5\),\(^{16\text{-}17}\) however, have attempted to include the important influence of finite radial geometry in a fully self-consistent manner, and these analyses\(^5\),\(^{16\text{-}17}\) have indicated that the relative positioning of electron beam radius \((\hat{R}_b)\) to conducting wall radius \((R_c)\) can indeed have a large effect on the linear growth rate and the detailed stability properties.

The longitudinal magnetic wiggler configuration\(^1\)\(^{-4}\) has been identified\(^1\) as a strong candidate for coherent radiation generation at frequencies significantly higher than those generated by the cyclotron maser instability (assuming the same average axial field \(B_0\)). In the present article, we investigate the influence of finite radial geometry on the longitudinal wiggler free electron laser instability.\(^1\)\(^{-4}\) The analysis is carried out for a thin, tenuous electron beam propagating down the axis of a multiple-mirror (undulator) magnetic field (Sec. II and Fig. 1). It is assumed that \(k_0^2\hat{R}_b^2<1\) and that the amplifying radiation field has TE-mode polarization with perturbed field components \((\hat{E}_0, \hat{B}_r, \hat{B}_z)\). Here, \(\hat{R}_b\) is the beam radius, \(\lambda_0 = 2\pi/k_0 = \text{const.}\) is the wavelength of the wiggle in the axial magnetic field, and the conducting wall is located at radius \(r = R_c\). A very important feature of the linear stability analysis (Secs. III and IV) is that the positioning of the beam radius relative to the conducting
wall radius (as measured by $\hat{R}_b / R_c$, say) can have a large influence on the
growth rate and detailed stability properties relative to the case where
the system is treated as infinite and uniform $^1$ in the transverse direction.

To briefly summarize, in Sec. II we describe the equilibrium
properties of a thin, tenuous electron beam propagating down the axis of
a multiple-mirror magnetic field. Equilibrium self fields are neglected,
and the vacuum magnetic field is approximated by [Eq. (3)]$^1$

$$B_z^0(r,z) = B_0 \left[ 1 + \frac{\delta B}{B_0} \sin k_0 z \right],$$

$$B_r^0(r,z) = 0,$$

for $k_0 R_b << 1$. Beam equilibrium properties ($\partial / \partial t = 0$) are investigated for
the choice of self-consistent equilibrium distribution function [Eq. (6)]$^3$

$$f_b^0(\chi, \mathcal{R}) = \frac{\hat{n}_b}{\pi} \delta(p_{\perp}^2 - 2 \gamma_b \hat{m}_b P_\theta - 2 \gamma_b m_{\perp} \hat{m}_b) \delta(p_z - \gamma_b m v_b),$$

where $p_{\perp}^2 = p_r^2 + p_\theta^2$, $p_z$ is the axial momentum, $P_\theta$ is the canonical angular
momentum, and $\hat{n}_b$, $\gamma_b$, $\omega_b$, $\hat{m}_b$, $m_{\perp}$ and $v_b$ are positive constants. Here $\gamma_b m^2$
is the characteristic energy of a beam electron. For small wiggler
amplitude ($\delta B / B_0 << 1$) and a slowly rotating electron beam with $\omega_b << \omega_{cb} = eB_0 / \gamma_b m c$, it is found that $f_b^0(\chi, \mathcal{R})$ can be approximated by [Eq. (16)]

$$f_b^0(\chi, \mathcal{R}) = \frac{\hat{n}_b}{\pi} \left[ p_{\perp}^2 - (\gamma_b m \hat{v}_{\perp})^2 \right] \delta(p_z - \gamma_b m v_b),$$

where $\hat{v}_{\perp}^2 = 2 \hat{m}_b / \gamma_b m$. In this case, the axial modulation of the beam
envelope is negligibly small with $R_b(z) = \hat{R}_b = \text{const.}$ [Eqs. (10) and (14)], and
the beam density is uniform with $n_b^0(r) = \hat{n}_b$ over the interval $0 < r < \hat{R}_b$
[Eq. (9)]. The particle trajectories in the equilibrium field configur-ation (3) are also described in Sec. II [Eqs. (17)-(20)].
Stability properties are investigated in Secs. III and IV for TE-mode perturbations about the choice of self-consistent solid-beam equilibrium specified in Eq. (16). Assuming perturbed field components \( \hat{\delta E}_\theta, \hat{\delta E}_r, \hat{\delta E}_z \), the linearized Vlasov-Maxwell equations [Eqs. (24)-(25)] are analyzed using techniques established in recent investigations\(^{37-39}\) of the influence of finite radial geometry on the cyclotron maser instability. In particular, for a tenuous electron beam, we approximate the \( r \)-dependence of \( \hat{\delta E}_\theta(r,z) \) by the vacuum waveguide solution, \( J_1(\alpha_{0\lambda} r/R_c) \), where \( \alpha_{0\lambda} \) is the \( \lambda \)'th zero of \( J_1(\alpha_{0\lambda}) = 0 \) [Eq. (30)]. After considerable algebraic manipulation, this gives the matrix dispersion equation [Eq. (43)]

\[
\left( \frac{\omega^2}{c^2} - k^2 - \frac{\alpha_{0\lambda}^2}{R_c^2} \right) + \sum_{n=-\infty}^{\infty} \chi_{n,n}(k,\omega) \hat{\delta E}_\theta(k) + \sum_{N \neq 0}^{\infty} \sum_{n=-\infty}^{\infty} \chi_{n-N,n}(k+Nk_0,\omega) \hat{\delta E}_\theta(k+Nk_0) = 0,
\]

where the susceptibility \( \chi_{m,n}(k,\omega) \) is defined in Eq. (50) for the choice of radially confined equilibrium distribution \( f_b^0(\chi,\nu) \) in Eq. (16). For sufficiently small wiggler amplitude, the off-diagonal terms in Eq. (43) can be neglected, and the dispersion relation is approximated by [Eq. (47)]

\[
\left( \frac{\omega^2}{c^2} - k^2 - \frac{\alpha_{0\lambda}^2}{R_c^2} \right) + \sum_{n=-\infty}^{\infty} \chi_{n,n}(k,\omega) = 0.
\]

The striking feature of the definition of \( \chi_{m,n}(k,\omega) \) in Eq. (50) is the strong dependence of the integrand on radial coordinate \( r \). For the case of small energy variation over the beam cross section, we obtain the approximate expression for \( \chi_{n,n}(k,\omega) \) given by [Eq. (55)].
\[ \chi_{n,n}(k,\omega) = -\frac{1}{4} \frac{\omega_{pb}^2}{c^2} \sum_n \left( \frac{\omega_{cb}}{k_0 V_b B_0} \right) \times \left( \frac{g_1 f_1(\omega)}{[\omega-(k+nk_0)V_b-\omega_{cb}]^2} - \frac{\hat{\nu}_{1b}^2}{c^2} \frac{g_2 f_2(\omega)}{[\omega-(k+nk_0)V_b-\omega_{cb}]^2} \right) + \left( \omega_{cb} + \omega_{cb} \right) \right] , \]

where \( f_1(\omega) \) and \( f_2(\omega) \) are defined in Eqs. (56) and (57), and \( g_1 \) and \( g_2 \) are the geometric factors defined in Eqs. (53) and (54) (see also Fig. 2).

In Sec. IV, we obtain approximate analytic and numerical solutions to the diagonal dispersion relation (47) for \( \chi_{n,n}(k,\omega) \) specified by Eq. (55). Several points are noteworthy from the stability analysis. First, for a given harmonic number \( n \), the characteristic maximum growth rate [Eq. (68)] is largest whenever the argument of \( J_n \) corresponds to the first zero of \( J_n'(x) = 0 \), i.e., when

\[ \frac{\omega_{cb}}{k_0 V_b B_0} = \alpha_{n,1} , \]

where \( \alpha_{n,1} \) is the first zero of \( J_n'(x) = 0 \). Second, the characteristic maximum growth rate scales as \( (\hat{\nu}_{1b}/c)^{2/3} n_0^{1/3} \), which can lead to substantial gain for the longitudinal wiggler free electron laser. Third, there is a strong dependence of stability properties on the positioning of the beam radius (\( R_b \)) relative to the conducting wall radius (\( R_c \)). In particular, the growth rate \( \Im \omega \) increases as \( \hat{R}_b/R_c \) is increased, and the detailed dependence of \( \Im \omega \) on \( \hat{R}_b/R_c \) is examined numerically in Sec. IV. Another important feature of the results is
that the instability is inherently broadband in the sense that many harmonics are unstable, even when \((\omega_{cb}/k_0v_b)(\delta B/B_0)\) is chosen to maximize emission for a particular value of \(n\).

Finally, also in Sec. IV, we investigate stability properties in the limiting case where \(\delta B = 0\). This corresponds to the cyclotron maser instability for perturbations about the solid electron beam equilibrium \(f^0_b(\chi, R)\) specified by Eq. (16). The numerical results for \(\delta B = 0\) also show a strong dependence on radial geometry \((R_b/R_c)\).
II. EQUILIBRIUM MODEL AND ASSUMPTIONS

A. Equilibrium Field Configuration

In the present analysis, a tenuous electron beam propagates
along the axis of a multiple-mirror (undulator) magnetic field with
axial periodicity length \( \lambda_0 = \frac{2\pi}{k_0} \) and axial and radial vacuum
magnetic fields, \( B_z^0(r,z) \) and \( B_r^0(r,z) \), given by

\[
\begin{align*}
B_z^0(r,z) &= B_0 \left[ 1 + \frac{\delta B}{B_0} I_0(k_0 r) \sin k_0 z \right], \\
B_r^0(r,z) &= -\delta B I_1(k_0 r) \cos k_0 z,
\end{align*}
\]

(1)

where \( I_n(k_0 r) \) is the modified Bessel function of the first kind of
order \( n \), and \( \frac{\delta B}{B_0} < 1 \) is related to the mirror ratio \( R \) by
\( R = \frac{(1+\delta B/B_0)/(1-\delta B/B_0)}{(1+\delta B/B_0)/(1-\delta B/B_0)} \). In circumstances where the beam radius \( R_b \) is
sufficiently small that

\[
k_0^2 R_b^2 \ll 1, \quad (2)
\]

and the oscillatory field amplitude \( \delta B \) is small with \( \delta B/B_0 < 1 \),
then the leading-order oscillation (wiggle) in the applied field is
primarily in the axial direction, with \( B_z^0 = O(k_0 r \delta B/B_0) B_0 \). Within
the context of Eq. (2), the equilibrium magnetic field components
can be approximated by

\[
\begin{align*}
B_z^0(r,z) &= B_0 \left[ 1 + \frac{\delta B}{B_0} \sin k_0 z \right], \\
B_r^0(r,z) &= 0,
\end{align*}
\]

(3)
in the beam interior where $r < R_b < k_0^{-1}$.

Assuming a tenuous electron beam with negligibly small equilibrium self fields, then the electron motion in the longitudinal wiggler field specified by Eq. (3) is characterized by four single-particle constants of the motion. These are:

\[ p_z', \]

\[ p^2 = p_r^2 + p_\theta^2, \]

\[ \gamma mc^2 = (m^2c^4 + c^2p_\perp^2 + c^2p_z^2)^{1/2}, \]  
\[ (4) \]

\[ p_\theta = r\left[p_\theta - \frac{e}{c}A^0_\theta(r,z)\right], \]

where $p_z$ is the axial momentum, $p_\perp$ is the perpendicular momentum, $\gamma mc^2$ is the electron energy, and

\[ A^0_\theta(r,z) = \frac{1}{2} rB_0 \left[ 1 + \frac{\delta B}{B_0} \sin k_0 z \right], \]  
\[ (5) \]

is the $\theta$-component of vector potential consistent with Eq. (3). Here, $-e$ is the electron charge, $m$ is the electron rest mass, and $c$ is the speed of light in vacuo. Note that $\gamma mc^2 = \text{const.}$ can be constructed from the constants of the motion $p_z$ and $p^2$, which are independently conserved.

It is important to keep in mind that the validity of the single-particle constants of the motion in Eq. (4) assumes that $k_0^2 r^2 \ll 1$, $\delta B / B_0 < 1$, and that the oscillatory radial magnetic field $B^0_r = -(\delta B / 2) k_0 r \cos k_0 z$ can be approximated by $B^0_r = 0$ [Eq. (3)]. To determine the range of
validity of this approximation, we have also calculated\(^1\) (in an
iterative sense) the leading-order corrections to the longitudinal
and transverse orbits, treating the magnetic force \((-e/c)v\times B_r^0\) as
a small correction.

B. Beam Equilibrium Properties

The TE-mode stability analysis in Sec. III is carried out for
perturbations about the self-consistent equilibrium distribution

\[
\frac{f^0_b(x,p)}{\pi} = \frac{\hat{n}_b}{\pi} \delta(p^2 - 2\gamma_b m\omega_b p^2 - 2\gamma_b m^2 T_{1b}) \delta(p_z - \gamma_b m V_b),
\]

where \(\hat{n}_b\), \(\hat{T}_{1b}\), \(\omega_b\) and \(V_b\) are constants, \(\gamma_b m^2 = \text{const.}\) is the
classical energy of a beam electron, and \(\hat{V}_{1b}\) is defined by
\(\hat{V}_{1b} = (2\hat{T}_{1b}/\gamma_b m)^{1/2}\). Making use of Eq. (4), it is readily shown that

\[
p^2 - 2\gamma_b m\omega_b p^2 = p^2_r + (p^2 - \gamma_b m\omega_b r)^2
\]

\[
+ \gamma_b m^2 r^2 \omega_b \left\{ \omega_{cb} \left[ 1 + \frac{\delta B}{B_0} \sin k_0 z \right] - \omega_c \right\},
\]

where \(\omega_{cb} = eB_0/\gamma_b m c\) is the relativistic cyclotron frequency. From
Eqs. (6) and (7), it readily follows that the average axial and
azimuthal momentum of the beam electrons are given by

\[
\langle p_z \rangle = \frac{\int d^3 p f^0_b}{\int d^3 p f^0_b} = \gamma_b m V_b,
\]

\[
\langle p_\theta \rangle = \frac{\int d^3 p p_\theta f^0_b}{\int d^3 p f^0_b} = \gamma_b m \omega_b r.
\]

Moreover, it can be shown from Eqs. (6) and (7) that \(f^0_b(x,p)\) corres-
ponds to a sharp-boundary equilibrium with density profile \( n_b^0(\chi) = \int d^3 p f_b^0 \) given by

\[
n_b^0(r, z) = \begin{cases} 
\hat{n}_b = \text{const.}, & 0 < r < R_b(z), \\
0, & r > R_b(z).
\end{cases}
\]  

(9)

Here, the radial boundary \( R_b(z) \) of the electron beam is defined by

\[
R_b^2(z) = \frac{\hat{V}_{1b}^2}{\omega_b [\omega_c [1 + (\delta B/B_0) \sin k_0 z] - \omega_b]},
\]  

(10)

where \( \hat{V}_{1b} = 2T_{1b}/\gamma_m \). From Eq. (10), \( \omega_b \) is required to be in the range

\[
0 < \omega_b < \omega_c [1 - \delta B/B_0],
\]  

(11)

for a radially confined equilibrium to exist. Moreover, the maximum beam radius \( [R_b]_{\text{MAX}} \) occurs for \( k_0 z = (2n+1)\pi/2, n = \pm 1, \pm 2, \ldots \).

Introducing the effective thermal Larmor radius \( r_{Lb} = \hat{V}_{1b}/\omega_c \), the condition \( k_0^2 [R_b]_{\text{MAX}}^2 \ll 1 \) can readily be expressed as

\[
k_0^2 r_{Lb}^2 \ll \frac{\omega_b}{\omega_c} \left( 1 - \frac{\delta B}{B_0} - \frac{\omega_b}{\omega_c} \right).
\]  

(12)

The stability analysis in Sec. III is carried out for the case where the beam rotation is slow with

\[
\omega_b \ll \omega_c,
\]  

(13)

and the wiggler amplitude is small with \( \delta B/B_0 \ll 1 \). In this case,
the axial modulation of the beam radius in Eq. (10) is very weak, and \( R_b(z) \) can be approximated by the constant value

\[
R_b(z) = \hat{R}_b = \left( \frac{\hat{\nu}_b^2}{\omega_b \omega_{cb}} \right)^{1/2}.
\]  

(14)

Moreover, consistent with Eqs. (13) and (14), it is valid to approximate \( p_\theta = -\gamma_b m_\omega \omega_{cb} r^2/2 \) in Eq. (7), which gives

\[
p^2 - 2\gamma_b m_\omega \omega_{cb} p_\theta = 2\gamma_b m_T^2
\]

\[
= p^2 - \left( \gamma_b m_{T_b} \right)^2 \left( 1 - r^2/R_b^2 \right)
\]

(15)

for \( \omega_b << \omega_{cb} \) and \( \delta B << B_0 \). The equilibrium distribution function in Eq. (6) can then be expressed to the required accuracy as

\[
f^0_b(x,p) = \frac{n_b}{\pi} \delta \left[ p^2 - \left( \gamma_b m_{V_b} \right)^2 \left( 1 - r^2/R_b^2 \right) \right] \delta(p_z - \gamma_b \omega_{V_b}),
\]  

(16)

where \( p^2 = p_x^2 + p_\theta^2 \). Equation (16) readily gives the rectangular density profile in Eq. (9) with constant beam radius equal to \( \hat{R}_b \).

Note from Eq. (16) that the equilibrium distribution function has an inverted population \(^1\) in \( p_\perp \) with \( f^0_b = \text{const.} \times \delta \left[ p^2 - p^2_\perp(r) \right] \delta(p_z - \gamma_b \omega_{V_b}), \) where \( p^2_\perp(r) = \left( \gamma_b m_{V_b} \right)^2 \left( 1 - r^2/R_b^2 \right) \).

C. Particle Trajectories in the Equilibrium Fields

The orbit equations for an electron moving in the axial magnetic field \( B_0^0(z) = B_0 + \delta B \sin k_0 z \) described by Eq. (3) are given by \( dp_x'/dt' = -(e/c)v_{x}^0(z'), dp_y'/dt' = (e/c)v_{y}^0(z') \) and \( dp_z'/dt' = 0 \), where \( p(t') = \gamma \omega' \omega(t') \) and \( \gamma = (1 + r^2/\omega^2 c^2)^{1/2} = \text{const.} \) The axial trajectory
(z', p') that passes through the phase space point (z, p_z) at time t'=t is given by

\[ p'_z = p_z, \quad z' = z + v_z \tau, \]  

(17)

where \( \tau = t'-t \) and \( v_z = p_z / \gamma m = \text{const.} \) is the axial velocity. Defining \( v'_x(t) = v'_x(t') + iv'_y(t') \) and making use of Eq. (17), it is straightforward to show that \( v'_+(t') \) satisfies

\[ \frac{d}{dt'} v'_+ = i \omega_c \left( 1 + \frac{\delta B}{B_0} \sin(k_0 z + k_0 v_z \tau) \right) v'_+, \]  

(18)

where \( \omega_c = eB_0 / \gamma mc \) is the relativistic cyclotron frequency for electron motion in the average field \( B_0 \). Integrating Eq. (18) with respect to \( t' \) and enforcing \( v'_+(t'=t) = v_x + iv_y = v_1 \exp(i \phi) \), where \((v_x, v_y) = (v_1 \cos \phi, v_1 \sin \phi)\) is the perpendicular velocity at time \( t'=t \), gives

\[ v'_+(t') = v_1 \exp \left( i \phi + i \omega_c \tau \right) \]

\[ + i \omega_c \frac{\delta B}{B_0} \frac{\cos k_0 z - \cos(k_0 z + k_0 v_z \tau)}{k_0 v_z}. \]  

(19)

From Eq. (19), we note that \( |v'_+(t')| = \text{const.} \), as expected. However, the individual transverse velocity components, \( v'_x(t') \) and \( v'_y(t') \), can be strongly modulated as a function of \( z \) and \( t' \) by the longitudinal wiggler field \( \delta B \sin k_0 z \). Depending on the size of \( \delta B / B_0 \), this can lead to a significant enhancement of radiation emission relative to the case where \( \delta B = 0 \).

For future reference, it is convenient to Fourier decompose the \( k_0 z \) dependence in Eq. (19), making use of the Bessel function identity...
\[ \exp(ib \cos \alpha) = \sum_{m=-\infty}^{\infty} J_m(b) \exp(-im\alpha + im\pi/2), \]

where \( J_m(b) \) is the Bessel function of the first kind of order \( m \).

This gives

\[ v'_t(t') = v_1 \exp(i\phi) \sum_{m,n} J_m \left( \frac{\omega_c}{k_0 v_z} \frac{\delta B}{B_0} \right) J_n \left( \frac{\omega_c}{k_0 v_z} \frac{\delta B}{B_0} \right) (i)^{n-m} \]

\[ \times \exp\left[i(\omega_c t + mk_0 v_z t')\right] \exp\left[i(m-n)k_0 z\right], \]

where \( \sum_{m,n} \) denotes \( \sum_{m=-\infty}^{\infty} \sum_{n=-\infty}^{\infty} \). From Eq. (20), for \( (\omega_c/k_0 v_z)(\delta B/B_0) \) of order unity, we note that the temporal modulation of the perpendicular velocity can be strong at harmonics of \( k_0 v_z = k_0 V_b \). Finally, when Eq. (20) is integrated with respect to \( t' \) to determine the transverse particle orbit \( x'(t') + iy(t') \), we note that there are resonant contributions proportional to \( (\omega_c + mk_0 v_z)^{-1} \). In this regard, the present analysis assumes that \( v_z = V_b \) is sufficiently far removed from cyclotron resonance (with \( \omega_c + mk_0 V_b \neq 0 \)) that the particle orbits do not exhibit large (secular) transverse excursions. 1
III. TE-MODE STABILITY PROPERTIES

A. Linearized Vlasov-Maxwell Equations

For the equilibrium configuration discussed in Sec. II, we now make use of the linearized Vlasov-Maxwell equations to investigate stability properties for electromagnetic perturbations with TE-mode polarization. It is assumed that a conducting wall is located at radius \( r = R_c > R_b \). Moreover, perturbed quantities are expressed as

\[
\delta \psi(x,t) = \delta \psi(x) \exp(-i\omega t),
\]

where \( \text{Im} \omega > 0 \) corresponds to instability. We consider azimuthally symmetric (\( \partial / \partial \theta = 0 \)) TE-mode perturbations with electromagnetic field components

\[
\delta \hat{E}_\phi(x) = \delta \hat{E}_\theta(r,z) \hat{e}_\theta, \quad (21)
\]

\[
\delta \hat{B}_\phi(x) = \delta \hat{B}_r(r,z) \hat{e}_r + \delta \hat{B}_z(r,z) \hat{e}_z, \quad (22)
\]

where \((\hat{e}_r, \hat{e}_\theta, \hat{e}_z)\) are unit vectors in the \((r, \theta, z)\) directions. The Maxwell equations for \( \delta \hat{E} \) and \( \delta \hat{B} \) are given by

\[
\nabla \times \delta \hat{E} = \frac{i\omega}{c} \delta \hat{B}, \quad (22)
\]

\[
\nabla \times \delta \hat{B} = -\frac{4\pi e}{c} \int d^3p \gamma \delta \hat{f}_b - \frac{i\omega}{c} \delta \hat{E}, \quad (23)
\]

where \( \delta \hat{J}(x) = -e \int d^3p \gamma \delta \hat{f}_b \) is the perturbed current density, and \( \delta \hat{f}_b(r,z,p) \) is the perturbed distribution function. From Eqs. (21) and (22), \( \delta \hat{B}_z(r,z) \)
and \(\delta B_r(r,z)\) are related to \(\delta E_\theta(r,z)\) by

\[
\delta \hat{B}_z = \frac{ic}{\omega r} \frac{\partial}{\partial r} (r \delta \hat{E}_\theta),
\]

\[
\delta \hat{B}_r = \frac{ic}{\omega} \frac{\partial}{\partial z} \delta \hat{E}_\theta.
\] (24)

Moreover, substituting Eq. (22) into Eq. (23) and taking the \(\theta\)-component gives

\[
\left( \frac{\omega^2}{c^2} + \frac{1}{r} \frac{\partial}{\partial r} r \frac{\partial}{\partial r} - \frac{1}{r^2} + \frac{\partial^2}{\partial z^2} \right) \delta \hat{E}_\theta(r,z)
\]

\[
= \frac{4\pi i\omega}{c^2} \int d^3p \, v_\theta \delta \hat{f}_b(r,z,p),
\] (25)

which relates \(\delta \hat{E}_\theta(r,z)\) to the perturbed azimuthal current density

\[
\delta J_\theta(r,z) = -e \int d^3p \, v_\theta \delta \hat{f}_b.
\]

Making use of the method of characteristics, the linearized Vlasov equation for \(\delta f_b(r,z,p,t) = \delta \hat{f}_b(r,z,p) \exp(-i\omega t)\) can be integrated to give

\[
\delta \hat{f}_b(r,z,p) = e \int_{-\infty}^{t} dt' \exp[-i\omega(t'-t)]
\]

\[
\times \left[ \delta \hat{E}(\chi') + \frac{\chi' \times \delta \hat{B}(\chi')}{} \cdot \frac{\partial}{\partial p} f^0_b(\chi',p'), \right]
\] (26)

where \((\chi', p')\) are the particle trajectories in the equilibrium field configuration (Sec. II.C) that pass through the phase space point \((\chi, p)\) at time \(t'=t\), and \(f^0_b(\chi, p)\) is the equilibrium distribution function. We first simplify Eq. (26) for the general class of self-consistent Vlasov equilibria (Sec. II.B),
\[ f_b^0(\chi, \rho) = f_b^0(\rho_1^2 - 2\gamma_b m \nu_b \rho_\theta, \rho_z), \quad (27) \]

where the perturbed electromagnetic fields have the components shown in Eq. (21). After some straightforward algebra, the perturbed distribution function can be expressed as

\[
\delta f_b(r, z, \rho) = 2e \left. \frac{3f_b^0}{\partial \rho_1^2} \right|_{-\infty}^{0} \int d\tau \exp(-i\omega \tau) \left\{ \left[ \delta E_\theta(r', z') \right] + \frac{1}{c} \nu' \delta B_r(r', z') \right\} \]

\[
\times \left( p_\theta' - \gamma_b m \nu_b \nu_z \right) + \gamma_b m \nu_b \nu_z \frac{1}{c} \nu' \delta B_z(r', z') \right\} \quad (28)
\]

\[
- e \left. \frac{3f_b^0}{\partial \rho_z} \right|_{-\infty}^{0} \int d\tau \exp(-i\omega \tau) \frac{1}{c} \nu' \delta \hat{B}_r(r', z') ,
\]

where \( \tau = t' - t \). In obtaining Eq. (28), use has been made of the fact that \( \frac{\partial f_b^0}{\partial \rho_1^2} \) and \( \frac{\partial f_b^0}{\partial \rho_z} \) are constant (independent of \( t' \)) along a particle trajectory in the equilibrium field configuration. Moreover, from Sec. II.B, \( \nu_z' = \nu_z = \frac{p_z}{\gamma m} \) and \( \nu' = \gamma = \left(1 + \frac{\nu_z^2}{m c^2}\right)^{1/2} \) are independent of \( t' \) in Eq. (28), and the axial orbit is given by \( z' = z + \nu_z t \).

In addition, the transverse velocities \( \nu'_r = \frac{dr'}{dt'} \) and \( \nu'_\theta = \frac{r'd\theta'}{dt'} \) can be determined from Eq. (19), subject to the boundary conditions \( \nu_r'(t' = t) = \nu_r, \nu'_\theta(t' = t) = \nu_\theta, r'(t' = t) = r \) and \( \theta'(t' = t) = \theta \).

Equation (28) simplifies considerably in the case of very slow beam rotation \( (\omega_b \ll \omega_{cb}) \) and weak wiggler field \( (\delta B \ll B_0) \) discussed in Sec. II.B. Neglecting the terms proportional to \( \omega_b \) in Eq. (28), and expressing \( \delta \hat{B}_r \) in terms of \( \delta \hat{E}_\theta \) [Eq. (24)], we obtain

\[
\delta f_b(r, z, \rho) = 2e \left. \frac{3f_b^0}{\partial \rho_1^2} \right|_{-\infty}^{0} \int d\tau \exp(-i\omega \tau)p_\theta' \delta \hat{E}_\theta(r', z')
\]

\[
+ \frac{i e}{\gamma m \nu_b} \left( 2p_z \frac{3f_b^0}{\partial \rho_z^2} - \frac{\partial f_b^0}{\partial \rho_z} \right) \left. \int d\tau \exp(-i\omega \tau)p_\theta' \delta \hat{E}_\theta(r', z') , \quad (29)
\]
where \( z' = z + v_z \tau \). In general, Eq. (29) is to be substituted into Eq. (25) and the resulting equation solved as an eigenvalue equation for \( \delta E_\theta (r,z) \) and \( \omega \).

\[ \delta E_\theta (r,z) = \delta E_\theta (z) J_1 (\alpha_{0z} r / R_c) , \quad (30) \]

where \( \alpha_{0z} \) is the \( l' \)th zero of \( J_1 (\alpha_{0z}) = 0 \), and \( \delta E_\theta (r=R_c,z) = 0 \) at the conducting wall. Here, \( J_n (x) \) is the Bessel function of the first kind of order \( n \). Taylor expanding the \( z' \)-dependence of \( \delta E_\theta (r',z') \) in Eq. (29) according to

\[ \delta E_\theta (z') = \sum_{k=-\infty}^{\infty} \delta E_\theta (k) \exp (ikz + ikv_z \tau) , \quad (31) \]

where \( k=2\pi n/L \) and \( L \) is the periodicity length in the \( z \)-direction, we readily find

\[ \delta \hat{f}_b (r,z,p) = e \sum_k \delta E_\theta (k) \exp (ikz) \left\{ 2 \left( 1 - \frac{kv_z}{\omega} \right) \frac{\partial f_0^b}{\partial p_1^b} + \frac{k}{\gamma \omega} \frac{\partial f_0^b}{\partial p_z} \right\} \]

\[ \times \int_0^0 \exp (-i\omega \tau + ikv_z \tau) p_0^b J_1 (\alpha_{0z} r' / R_c) \].

We substitute Eqs. (30) and (32) into Eq. (25), make use of
\( \{ r^{-1} (\partial/\partial r) \{ r (\partial/\partial r) \} \} - r^{-2} J_1 (\alpha_0 r/R_c) = -(\alpha_0^2 / R_c^2) J_1 (\alpha_0 r/R_c) \), and operate with \( \int_0^{R_c} dr \ r J_1 (\alpha_0 r/R_c) \ldots \). This gives

\[
\left( \frac{2}{c^2} - \frac{\alpha_0^2}{R_c^2} + \frac{2}{\partial z^2} \right) \delta E_\theta (z)
\]

\[
= \left( \frac{4 e^2 i\omega / c^2}{(R_c/2)^2 (\alpha_0)^2 / 2} \right) \int_0^{R_c} dr \ r J_1 \left( \frac{\alpha_0 r}{R_c} \right) \sum_k \delta E_\theta (k) \exp(ikz)
\]

\[
\times \int d^3 p \ \delta \left( \frac{k}{\omega} \right) \left( 1 - \frac{\nu \omega}{\omega} \right) \frac{\partial f_0^0}{\partial p_1} + \frac{k}{\gamma m \omega} \frac{\partial f_0^0}{\partial p_z}
\]

\[
\times \int_0^{R_c} d\tau \ \exp(-i\omega \tau + ik v_z \tau) p'_0 J_1 (\alpha_0 r'/R_c)
\]

where use has been made of \( \int_0^{R_c} dr \ r J_1^2 (\alpha_0 r/R_c) = (R_c/2)^2 J_2^2 (\alpha_0) \).

We now evaluate the orbit integral

\[
I = \int_0^0 d\tau \ \exp(-i\omega \tau + ik v_z \tau) p'_0 J_1 (\alpha_0 r'/R_c)
\]

The azimuthal momentum \( p'_0 \) is expressed as \( p'_0 = p_1 \sin(\phi' - \phi') \), where

\( p_1 = p_0 = \gamma m v_1 \) is constant (independent of \( t' \)) for the equilibrium field configuration described in Sec. II. Equation (34) then becomes

\[
I = p_1 \int_0^0 d\tau \ \exp(-i\omega \tau + ik v_z \tau) \sin(\phi' - \phi') J_1 (\alpha_0 r'/R_c)
\]

To simplify Eq. (35), we specialize to the case of small thermal Larmor radius, \( r_L^2 / r_b^2 \ll 1 \), and approximate the \( r' \) and \( \theta' \) orbits by \( (r', \theta') \approx (r, \theta) \). This is an excellent approximation for a slowly rotating beam with \( \omega_b / \omega_{cb} \ll 1 \), since \( r_L^2 / r_b^2 = \hat{v}_{ib}^2 / \omega_{cb}^2 \) \( r_b^2 = \omega_b / \omega_{cb} \ll 1 \) follows from Eq. (14). The orbit integral \( I \) in Eq. (35) can then be approximated by
\[ I = p_1 J_1 (a_0 r/R_c) \int_{-\infty}^{0} d\tau \exp(-i\omega \tau + ik v_z \tau) \] 
\[ \times \frac{1}{2i} \{ \exp[i(\phi' - \theta)] - \exp[-i(\phi' - \theta)] \}, \] 

where \( \phi' \) is the rapidly oscillating velocity phase defined by [Eq. (19)],

\[ \phi' = \phi + \omega_c \tau + \omega_c B_0 \left( \frac{\cos k_0 z - \cos (k_0 z + k_0 v_z \tau)}{k_0 v_z} \right). \] 

We substitute Eq. (37) into Eq. (36), make use of the Bessel function identity in Eq. (20) to expand \( \exp(\pm i\phi') \), and then carry out the integration over \( \tau \) for \( \text{Im} \omega > 0 \). After some straightforward algebra, this gives

\[ I = \frac{p_1 J_1 (a_0 r/R_c)}{2i} \sum_{n,m} J_n \left( \frac{\omega_c}{k_0 v_z} B_0 \right) J_m \left( \frac{\omega_c}{k_0 v_z} B_0 \right) \]
\[ \times \left\{ \frac{\exp[i(\phi-\theta)] \exp[-i(n-m)k_0 z](i)^{n-m+1}}{\omega-(k+m k_0) v_z - \omega_c} \right\}, \] 

where \( \omega_c = eB_0/\gamma mc \), \( v_z = p_z/\gamma m \) and \( \sum_{n,m} \) denotes \( \sum_{n=-\infty}^{\infty} \sum_{m=-\infty}^{\infty} \). In the eigenvalue equation (33), we express \( \int d^3p = \int_{-\infty}^{0} \int_{0}^{\infty} \int_{0}^{\infty} dp_1 dp \phi dp_z \) and carry out the required integration over \( \phi \), making use of \( v_\theta = (p_\phi/\gamma m) \sin(\phi - \theta) \) and the fact that \( f^0 = f^0 [p^2_\phi - (\gamma_m v_\phi)^2 (1 - r^2/R^2_b), p_z] \) is independent of \( \phi \) to the level of accuracy of Eq. (15). In particular, we readily obtain from Eq. (38)
\[
\int_0^{2\pi} d\phi v_\perp \sin(\phi - \theta) I
\] 

\[
= -\frac{2\pi p_\perp^2}{4\gamma m} J_1(\alpha_0 r/R_c) \sum_{n,m} J_n \left( \frac{\omega c}{k_0 v_z B_0} \right) J_m \left( \frac{\omega c}{k_0 v_z B_0} \right) \exp[-i(n-m)k_0 z] 
\]

\[
\times \left\{ \frac{(i)^{n-m}}{\omega - (k+mk_0)v_z - \omega_c} - \frac{(i)^{-n+m}}{\omega - (k+mk_0)v_z + \omega_c} \right\} .
\]

Substituting Eq. (39) into Eq. (33), the eigenvalue equation for \( \delta E_\theta(z) \) can be expressed as

\[
\left( \frac{\partial^2}{\partial z^2} - \frac{\alpha_0^2 \ell c^2}{2} + \frac{\omega^2}{c^2} \right) \delta E_\theta(z)
\]

\[
= -\sum_{k,m,n} \chi_{m,n}(k,\omega) \delta E_\theta(k)
\]

\[
\times \exp[i(k+mk_0-nk_0)z] ,
\]

where the susceptibility \( \chi_{m,n}(k,\omega) \) is defined by

\[
\chi_{m,n}(k,\omega) = \frac{1}{4} \left( \frac{4\pi e^2 / c}{2} \right) \int_0^R dr \int J_1^2(\alpha_0 r/R_c) \left( \frac{\omega c}{k_0 v_z B_0} \right) \left( \frac{\omega c}{k_0 v_z B_0} \right) \exp[-i(n-m)k_0 z]
\]

\[
\times \int d^3 p J_m \left( \frac{\omega c}{k_0 v_z B_0} \right) J_n \left( \frac{\omega c}{k_0 v_z B_0} \right) \left[ \frac{3f_0^0}{p_\perp^2} + k \left( \frac{3f_0^0}{p_\perp^2} - \frac{p_z}{p_\perp^2} \frac{3f_0^0}{p_\perp^2} \right) \right]
\]

\[
\times \frac{(i)^{n-m}}{\omega - (k+mk_0)v_z - \omega_c} - \frac{(i)^{-n+m}}{\omega - (k+mk_0)v_z + \omega_c} .
\]
In Eq. (41), \( v_L = p_L/\gamma m \), \( v_z = p_z/\gamma m \), \( \omega_c = eB_0/\gamma mc \) and \( \int d^3p = 2\pi \int_0^\infty dp_d p_d \int_0^\infty dp_z \).

Equations (40) and (41) should be compared with Eqs. (22) and (23) of Ref. 1. The major difference is that Eqs. (40) and (41) include finite radial beam geometry in a fully self-consistent manner, whereas Ref. 1 assumes an infinite uniform beam in the transverse direction.

The effects of finite radial geometry are manifest through the occurrence of the effective perpendicular wavenumber \( a_{0L} \) on the left-hand side of Eq. (40), as well as the \( r \)-integration over \( J_1^2(a_{0L}r/R_c) \) and the \( r \)-dependence of the equilibrium distribution function \( f_b^0 \) in Eq. (41) [see Eqs. (15) and (16)]. Fourier decomposing the left-hand side of Eq. (40) with respect to \( z \), and changing the \( k \)-summation variable on the right-hand side of Eq. (40) from \( k+mk_0-nk_0 \) to \( k \) gives

\[
\sum_k \left[ \frac{\omega^2}{c^2} - \frac{a_{0L}^2}{R_c^2} - k^2 \right] \delta \tilde{E}_\theta(k) \exp(ikz) \\
+ \sum_{k,m,n} \chi_{m,n} (k+mk_0-nk_0,\omega) \delta \tilde{E}_\theta(k+mk_0-nk_0) \exp(ikz)
\]

\[= 0.\]

Equation (42) gives the final dispersion equation

\[
D_0(k,\omega) \delta \tilde{E}_\theta(k) + \sum_{N \neq 0} \chi_N (k+Nk_0,\omega) \delta \tilde{E}_\theta(k+Nk_0) = 0 ,
\]

(43)

where \( \sum \) \(=\) \(\sum_{N=-\infty}^{-1}\) + \(\sum_{N=1}^{\infty}\), and \( D_0 \) and \( \chi_N \) are defined by

\[
D_0(k,\omega) = \left[ \frac{\omega^2}{c^2} - k^2 - \frac{a_{0L}^2}{R_c^2} \right] + \chi_0(k,\omega),
\]

(44)

and
The dispersion equation (43) can be used to investigate stability properties for a wide range of system parameters. To lowest-order, the stability analysis in Sec. IV is based on a diagonal approximation to Eq. (43), i.e.,

\[ D_0(k,\omega) = 0 , \]  

which neglects the coupling of \( \delta \mathcal{E}_\theta(k) \) to the higher harmonic dependence in \( \delta \mathcal{E}_\theta(k+Nk_0) \) for \( N \neq 0 \). Making use of Eqs. (44) and (45), the approximate dispersion relation (46) reduces to

\[
\left( \frac{\omega^2}{c^2} - k^2 - \frac{\alpha_0^2}{R_c^2} \right) + \sum_{n=-\infty}^{\infty} \chi_{n,n}(k,\omega) = 0 ,
\]

which is analyzed in Sec. IV.

C. Susceptibility for a Nonuniform Beam

We now evaluate the susceptibility \( \chi_{m,n}(k,\omega) \) defined in Eq. (41) for the specific choice of radially nonuniform beam equilibrium in Eq. (16). The evaluation of \( \chi_{m,n}(k,\omega) \) proceeds in a manner similar to Ref. 1 with the important difference that the \( p_\perp^0 \) - and \( p_z \) -integrations in Eq. (41) select spatially nonuniform values of \( p_\perp \) and \( \gamma mc^2 \) for the choice of \( f_b^0 \) in Eq. (16). In this regard, it is convenient to define
\[ \hat{p}_{ib} = \gamma_b \hat{v}_{ib}, \]
\[ p_{zb} = \gamma_b m v_b, \]
\[ \gamma_b = \left(1 + \frac{p_{zb}^2}{m^2 c^2}\right)^{1/2} = \left(1 - \frac{v_b^2}{c^2}\right)^{-1/2}. \]

(Heretofore, \( \gamma_b \) has been a convenient scale factor, with \( \gamma_b m c^2 \) a measure to the characteristic electron energy.) It is clear from Eq. (16) that the delta-function form of \( f_b^0 \) selects the values of perpendicular momentum \( p_\perp = p_{10}(r) \), total energy \( \gamma_m c^2 = \gamma_0(r) m c^2 \), perpendicular velocity \( v_\perp = p_{\perp}/\gamma_m = V_{\perp 0}(r) \), and axial velocity \( v_z = p_z/\gamma_m = V_{b0}(r) \), where

\[ p_{10}(r) \equiv \frac{\gamma_b}{\gamma_0(r)} \left(1 - \frac{r^2}{R_b^2}\right), \]
\[ \gamma_0(r) \equiv \gamma_b \left[1 + \frac{\hat{V}_{ib}}{c^2} \left(1 - \frac{r^2}{R_b^2}\right)\right]^{1/2}, \]
\[ V_{\perp 0}(r) \equiv \frac{\gamma_b}{\gamma_0(r)} \hat{V}_{ib} \left(1 - \frac{r^2}{R_b^2}\right)^{1/2}, \]
\[ V_{b0}(r) \equiv \frac{\gamma_b}{\gamma_0(r)} V_{b0}, \]

for \( 0 < r < \hat{R}_b \). Note from Eq. (49) that \( p_{10}(r) \) and \( V_{\perp 0}(r) \) are highly nonuniform across the beam cross-section, assuming maximum values on the axis of the beam \( (r=0) \), and minimum values of zero at the edge of the beam \( (r=\hat{R}_b) \). On the other hand, for \( \hat{V}_{ib}/c^2 \ll 1 \), the variation of \( \gamma_0(r) \) and \( V_{b0}(r) \) is relatively weak over the beam cross section.

Substituting Eq. (16) into Eq. (41) and carrying out the integrations over \( p_\perp \) and \( p_z \), we find after some straightforward but
tedious algebra that \( x_{m,n}(k,\omega) \) can be expressed as

\[
x_{m,n}(k,\omega) = \frac{1}{4} \frac{\omega_{pb}^2}{c^2} \frac{1}{[(R_c^2/2)J_2^2(\alpha_0^2)]} \int_0^{R_b} dr \frac{r}{\alpha_0 R_c} J_1^2\left(\frac{\alpha_0 r}{R_c}\right)
\]

\[
\times J_m\left(\frac{\omega_{cb} \delta E}{k_0 V_b B_0}\right) J_n\left(\frac{\omega_{cb} \delta E}{k_0 V_b B_0}\right) \frac{\gamma_b}{\gamma_0}
\]

\[
\times \left\{ \left(1\right)^{n-m} \frac{\omega_{-(k+nk_0)} V_b \gamma_b / \gamma_0^2 \omega_{cb} \gamma_b / \gamma_0}{2\left[\omega_{-(k+nk_0-mk_0)} V_b \gamma_b / \gamma_0\right]} \right. \\
+ \frac{V_{10}^2(r)}{c^2} \frac{(k+nk_0-mk_0)\epsilon^2 \gamma_b}{V_b \gamma_0} \left[ \omega_{-(k+nk_0-mk_0)} (k+nk_0) \epsilon^2 \right] \\
- \frac{V_{10}^2(r)}{c^2} \frac{1}{\omega_{-(k+nk_0)} V_b \gamma_b / \gamma_0^2 \omega_{cb} \gamma_b / \gamma_0} \left[ \omega_{-(k+nk_0-mk_0)} (k+nk_0) \epsilon^2 \right]
\]

\[
\left. + \left(\omega_{cb} - \omega_{cb}\right) \right\},
\]

where \( \omega_{pb}^2 = 4\pi \hbar e^2 / \gamma_b m, \omega_{cb} = eB / \gamma_b mc, \) and \( \gamma_0(r) \) and \( V_{10}(r) \) are defined in Eq. (49). Here, \( \epsilon_{m,n} \) is defined by

\[
\epsilon_{m,n} = \left\{ p_z \left[ \frac{\partial}{\partial p_z} \right] \ln \left[ J_n\left(\frac{e\delta B}{k_0 c p_z}\right) J_m\left(\frac{e\delta B}{k_0 c p_z}\right) \right] \left\{ p_z \gamma_b m V_b \right\}
\]

The \( r \)-dependence of the integrand in Eq. (50) is generally quite complicated. For present purposes, we assume \( V_{10}^2/c^2 < 1 \) and approximate \( \gamma_0(r) \approx \gamma_b \) in Eq. (50). This gives the approximate result
\[ \chi_{m,n}(k,\omega) = -\frac{1}{4} \frac{\omega^2}{c^2} \omega \left[ (R_c^2/2)J_2^2(\alpha_{0\xi}) \right] \int_0^{R_b} \frac{\hat{r}^2}{c^2} r \ J_1^2 \left( \frac{\alpha_{0\xi} \hat{r}}{R_c} \right) \]

\[ \times J_m \left( \frac{\omega_{cb}}{k_0 V_b} \right) J_n \left( \frac{\omega_{cb}}{k_0 V_b} \right) \]

\[ \times \left[ \frac{(i)^n m}{\omega - (k+nk_0) V_b - \omega_{cb}} \left\{ 2\left[ \omega - (k+nk_0-mk_0) V_b \right] \right. \]

\[ + \frac{\hat{V}_{1b}^2}{c^2} \left( 1 - \frac{r^2}{R_b^2} \right) \frac{(k+nk_0-mk_0)c^2}{V_b} \varepsilon_{m,n} \]

\[ - \frac{\hat{V}_{1b}^2}{c^2} \left( 1 - \frac{r^2}{R_b^2} \right) \frac{\omega - (k+nk_0) V_b - \omega_{cb} \omega_{cb}}{\omega - (k+nk_0) V_b - \omega_{cb}} \]

\[ + \left( \omega_{cb} \rightarrow -\omega_{cb} \right) \right] \] (52)

In Eq. (52), the \( r \)-dependence of the integrand is of the form \( rJ_1^2(\alpha_{0\xi} r/R_c) \) and \( rJ_1^2(\alpha_{0\xi} r/R_c)(1-r^2/R_b^2) \). We introduce the geometric factors \( g_1 \) and \( g_2 \) defined by

\[ g_1 = \frac{1}{\left[ (R_c^2/2)J_2^2(\alpha_{0\xi}) \right]} \int_0^{R_b} \frac{\hat{r}^2}{c^2} r \ J_1^2 \left( \frac{\alpha_{0\xi} \hat{r}}{R_c} \right) \]

\[ = \frac{\hat{R}_b^2}{R_c^2 J_2^2(\alpha_{0\xi})} \left[ J_1^2 \left( \frac{\alpha_{0\xi} \hat{R}_b}{R_c} \right) + \left( 1 - \frac{R_b^2}{R_c^2} \right) J_1^2 \left( \frac{\alpha_{0\xi} \hat{R}_b}{R_c} \right) \right] \] (53)

and

\[ g_2 = \frac{1}{\left[ (R_c^2/2)J_2^2(\alpha_{0\xi}) \right]} \int_0^{R_b} \frac{\hat{r}^2}{c^2} r \left( 1 - \frac{r^2}{R_b^2} \right) J_1^2 \left( \frac{\alpha_{0\xi} \hat{r}}{R_c} \right) \]

\[ = \frac{2\hat{R}_b^2}{3R_c^2 J_2^2(\alpha_{0\xi})} \left[ J_0^2 \left( \frac{\alpha_{0\xi} \hat{R}_b}{R_c} \right) + J_1^2 \left( \frac{\alpha_{0\xi} \hat{R}_b}{R_c} \right) \left( 1 - \frac{2R_b^2}{\alpha_{0\xi}^2 \hat{R}_b^2} \right) \right] \]

\[ - \frac{R_c}{\alpha_{0\xi} \hat{R}_b} J_0 \left( \frac{\alpha_{0\xi} \hat{R}_b}{R_c} \right) J_1 \left( \frac{\alpha_{0\xi} \hat{R}_b}{R_c} \right) \] (54)
Note from Eq. (53) that \( g_1 = 1 \) for a uniform density beam filling the waveguide \( (R_b/R_c = 1) \). On the other hand, for \( R_b = R_c \), it follows from Eq. (54) that \( g_2 = (2/3) \). Figure 2 shows plots of the geometric factors \( g_1 \) and \( g_2 \) versus \( R_b/R_c \) for several values of \( \lambda \).

Note that \( g_1 \) and \( g_2 \) increase monotonically for increasing \( R_b/R_c \).

Substituting Eqs. (53) and (54) into Eq. (52), we can simplify the expression for \( \chi_{m,n}(k,\omega) \) for general values of \( m \) and \( n \). In the approximate dispersion relation (47), however, only the diagonal terms are retained. For \( m=n \), Eqs. (52) - (54) give for the susceptibility

\[
\chi_{n,n}(k,\omega) = -\frac{1}{4} \frac{\omega_{pb}^2}{c^2} \sum_{n} \left( \frac{\omega_{cb}}{k_0 V_b \delta B} \right) \left( \frac{V_{1b}^2}{[\omega - (k+nk_0)V_b - \omega_{cb}]} - \frac{g_2 V_{1b}^2}{[\omega - (k+nk_0)V_b - \omega_{cb}]} \right)
\]

Here, \( \omega_{pb}^2 = 4\pi n_e^2/\gamma_b m \), \( \omega_{cb} = e\delta B/\gamma_b mc \), \( g_1 \) and \( g_2 \) are defined in Eqs. (53) and (54), and \( f_1(\omega) \) and \( f_2(\omega) \) are defined by (for \( m=n \))

\[
f_1(\omega) = 2(\omega - kV_b) + \frac{V_{1b}^2}{c^2} \frac{g_2 \frac{k\epsilon}{V_b}}{g_1} \epsilon_{n,n},
\]

\[
f_2(\omega) = \omega^2 - k(k+nk_0)c^2.
\]

In overall form, Eq. (56) is similar to the result obtained in Ref. 1 for the case of a uniform beam with infinite cross section. There are important differences, however, associated with the dependence of \( \chi_{n,n}(k,\omega) \) on the geometric factors \( g_1 \) and \( g_2 \).
IV. ANALYSIS OF DISPERSION RELATION

A. Approximate Dispersion Relation

Making use of the expression for $\chi_{n,n}(k,\omega)$ in Eq. (55), the approximate dispersion relation (47) for a tenuous beam can be expressed as

\[
\left( \frac{\omega^2}{c^2} - k^2 - \frac{a_{0 \ell}^2}{R_c^2} \right) = \frac{1}{4} \frac{\omega_p^2}{c^2} \sum_{n=0}^{\infty} J_2^2 \left( \frac{\omega_B}{k_0 V_b B_0} \frac{\delta B}{B_0} \right) \times \left[ \left( g_1 f_1(\omega) \frac{\dot{V}_{1b}}{c^2} \frac{g_2 f_2(\omega)}{[\omega-(k+nk_0)V_b-\omega_0^2 V_b] \cdot \omega_{cb} - c^2 (\omega-(k+nk_0)V_b-\omega_0^2 V_b)^2} \right) \right.
\]

\[
+ \left( \omega_{cb} + \omega_{cb} \right) \right].
\]

The dispersion relation (58) clearly has a very rich harmonic content, and Eq. (58) can be solved numerically retaining several terms in the summation over $n$. For present purposes, we assume that the harmonics in Eq. (58) are well isolated, and investigate stability behavior near cyclotron resonance with polarity

\[
\omega - (k+nk_0)V_b = \pm \omega_{cb},
\]

for a particular choice of harmonic number $n$. Equation (58) can then be approximated by

\[
(\omega^2 - c^2 k^2 - a_{0 \ell}^2 c^2 / R_c^2 ) [\omega - (k+nk_0)V_b - \omega_{cb}]^2
\]

\[
= \frac{1}{4} \omega_p^2 J_2 \left( \frac{\omega_{cb}}{k_0 V_b} B_0 \right) \times \left( g_1 f_1(\omega) [\omega - (k+nk_0)V_b - \omega_{cb}] + \frac{\dot{V}_{1b}}{c^2} g_2 f_2(\omega) \right),
\]

(60)
where \( g_1, g_2, f_1, \) and \( f_2 \) are defined in Eqs. (53), (54), (56), and (57).

For \( \omega = (k+nk_0)V_b + \omega_{cb} \), the first term on the right-hand side of Eq. (60) is negligibly small, and the dispersion relation can be approximated by

\[
(\omega^2 - c^2k^2 - c^2k_{L}^2) \left[ \omega - (k+nk_0)V_b - \omega_{cb} \right]^2
\]

\[
+ \frac{1}{4} g_2 \omega_{pb}^2 \frac{\hat{V}_{ib}^2}{c^2} J_n^2 \left( \frac{\omega_{cb}}{k_0 V_b} \frac{\delta \beta}{B_0} \right)
\]

\[
= \frac{1}{4} g_2 \omega_{pb}^2 \frac{\hat{V}_{ib}^2}{c^2} J_n^2 \left( \frac{\omega_{cb}}{k_0 V_b} \frac{\delta \beta}{B_0} \right) (knk_0c^2 - k_{L}^2 c^2).
\]

The dispersion relation (60) is solved numerically in Sec. IV.C, and analytic estimates of the instability growth rate are made in Sec. IV.B.

### B. Analytic Results

For a tenuous beam with \( (\omega_{pb}^2/c^2k^2)(\hat{V}_{ib}^2/c^2) \ll 1 \), we look for solutions to Eq. (61) near the simultaneous zeroes of

\[
\omega = \left( c^2k^2 + c^2k_{L}^2 \right)^{1/2},
\]

\[
\omega = (k+nk_0)V_b + \omega_{cb}.
\]

Here, \( k_{L} = \alpha_{0L}/R_c \) is the effective perpendicular wavenumber, and we have chosen the branch with positive frequency \( (\omega > 0) \) in Eq. (62).

Shown in Fig. 3 are plots of \( \omega/ck_0 \) versus \( k/k_0 \) obtained from Eq. (62) for the choice of parameters \( k_{L}/k_0 = 9.58, V_b/c = 0.866, \) and \( \omega_{cb}/ck_0 = 4.783, \) and several values of the harmonic number \( n \). Denoting the simultaneous
solutions to Eq. (62) by \((\omega_n, k_n)\), we find for the upshifted frequency and wavenumber

\[
\hat{\omega}_n = \gamma_b^2 (nk_0 v_b + \omega_{cb}) \left\{ 1 + \beta_b \left[ 1 - \frac{c^2 k_{IL}^2}{\gamma_b^2 (nk_0 v_b + \omega_{cb})^2} \right]^{1/2} \right\}, \tag{63}
\]

and

\[
\hat{k}_n = \gamma_b^2 (nk_0 v_b + \omega_{cb}) \frac{1}{c} \left\{ \beta_b + \left[ 1 - \frac{c^2 k_{IL}^2}{\gamma_b^2 (nk_0 v_b + \omega_{cb})^2} \right]^{1/2} \right\}, \tag{64}
\]

where \(\beta_b\) and \(\gamma_b\) are defined by \(\beta_b = v_b / c\) and \(\gamma_b = (1 - \beta_b^2)^{-1/2}\). Note that \((\hat{\omega}_n, \hat{k}_n)\) corresponds to the uppermost intersection points in Fig. 3. Moreover, for \(k_\perp \to 0\), Eqs. (63) and (64) reduce to the familiar results obtained in Ref. 1 for a uniform density beam with infinite transverse dimension \((R_b, R_c \to \infty)\). For solutions to exist, it is clear from Eqs. (63) and (64) that the inequality

\[
c^2 k_{IL}^2 = \frac{\alpha_0^2}{R_c^2} < \gamma_b^2 (nk_0 v_b + \omega_{cb})^2,
\tag{65}
\]

must be satisfied, which we assume to be the case in the remainder of Sec. IV.

For purposes of making an analytic estimate of the growth rate, we express \(\omega = \hat{\omega}_n + \delta \omega\) and \(k = \hat{k}_n + \delta k\) in Eq. (61), treating \((\omega_{pb}^2 / c^2 k_n^2) (\hat{v}_{lb}^2 / c^2)\) as a small parameter. To leading order, this gives

\[
\left( \delta \omega - c^2 \frac{\hat{k}_n}{\hat{\omega}_n} \delta k \right) \left\{ (\delta \omega - v_b \delta k)^2 + \frac{1}{4} g_{2n}^2 \omega_{pb}^2 \frac{\hat{v}_{lb}^2}{c^2} J_n^2 \right\} = \frac{1}{8} g_{2n}^2 \omega_{pb}^2 \frac{\hat{v}_{lb}^2}{c^2} J_n^2 \frac{(k_n nk_0 - k_{IL}^2) c}{(k_n^2 + k_{IL}^2)^{1/2}},
\tag{66}
\]
where $J_n^2$ denotes $J_n^2(\omega_{cb} B/k_0 V_b B_0)$, use has been made of $\hat{\omega}_n = (c^2 k_n^2 + c^2 k_{1\perp}^2)^{1/2}$ [Eq. (62)], and $(\hat{\omega}_n, k_n)$ are defined in Eqs. (63) and (64). As a simple analytic estimate of the characteristic maximum growth rate, we consider Eq. (66) for $\delta k = 0$. Typically, the $J_n^2$ contribution on the left-hand side of Eq. (66) makes a small contribution in comparison with the right-hand side, and Eq. (66) can be approximated by (for $\delta k = 0$),

$$
(\delta \omega)^3 = \frac{1}{9} \frac{c}{g_2 \omega_{pb}^2} \frac{\hat{V}_{1b}^2}{c^2} \frac{\hat{V}_{1b}^2}{c^2} \frac{(k_n k_0 - k_{1\perp}^2) c}{(k_n^2 + k_{1\perp}^2)^{1/2}}.
$$

(67)

For sufficiently short emission wavelength that $k_n k_0 > k_{1\perp}^2$, Eq. (67) gives

$$
\text{Im} \delta \omega = \frac{\sqrt{3}}{2} \Gamma_n = \frac{\sqrt{3}}{4} \left( \frac{g_2 \omega_{pb}^2}{c^2} \frac{V_{1b}^2}{c^2} \frac{(k_n k_0 - k_{1\perp}^2) c}{(k_n^2 + k_{1\perp}^2)^{1/2}} \right)^{1/3},
$$

(68)

$$
\text{Re} \delta \omega = - \frac{1}{2} \Gamma_n.
$$

Several points are noteworthy from Eq. (68). First, for a given harmonic number $n$, the characteristic maximum growth rate $\text{Im} \delta \omega$ defined in Eq. (68) will be largest whenever the argument of $J_n$ corresponds to the first zero of $J_n'(x) = 0$, i.e., when

$$
\frac{\omega_{cb}}{k_0 V_b B_0} = \alpha_{n,1},
$$

(69)

where $\alpha_{n,1}$ is the first zero of $J_n'(x) = 0$. Second, since $\text{Im} \delta \omega$ scales as $(\hat{V}_{1b}/c)^2/3^{1/3} n_b$, the growth rate for the longitudinal wiggler FEL can be substantial. Third, the growth rate increases as the geometric factor $g_2$ is increased (see also Fig. 2). Moreover, the free electron laser instability described by Eq. (61) is inherently
broadband in the sense that many harmonics are unstable, even when
\((\omega_{cb}/k_0 V_b)(\delta B/B_0)\) is chosen to maximize emission for a particular
value of \(n\) [Eq. (69)]. Finally, in the limit of very short emission
wavelength with \(\hat{k}_n k_0 \gg k_0^2\), it follows from Eq. (68) that \(\text{Im}\omega\) can
be approximated by

\[
\text{Im}\omega = \frac{\sqrt{3}}{4} \left( g_2 \omega_p^2 k_0 c \frac{V_{lb}^2 n^2}{c^2} \right)^{1/3}
\]

C. Numerical Results

The dispersion relation (60) is a fourth-order algebraic equation
for the complex eigenfrequency \(\omega\). Equation (60) has been solved
numerically over a wide range of system parameters. In this section,
we summarize selected numerical results for \(\delta B/B_0 \neq 0\) (longitudinal
wiggler free electron laser) and for \(\delta B = 0\) (cyclotron maser).

Longitudinal Wiggler Free Electron Laser: Shown in Figs. 4 and 5
are plots of the normalized growth rate \(\text{Im}\omega/k_0\) versus \(k/k_0\) obtained
numerically from Eq. (60). The parameters common to both Figs. 4 and 5
are \(k_0^2 = 0.1\), \(\gamma_b = 2\), \(\alpha_{0\beta} = 3.83\) (\(\ell = 1\)), \(\hat{V}_{lb} = 0.1\), \(V_b/c = 0.866\),
\(\omega_p/c_k = 0.25\), and \(\delta B/B_0 = 1/3\). In Fig. 4, we have chosen the parameter
\((\delta B/B_0)(\omega_{cb}/c_k) = \alpha_{1,1} = 1.841\), which maximizes the growth rate for \(n = 1\).
On the other hand, in Fig. 5 we have chosen \((\delta B/B_0)(\omega_{cb}/c_k) = \alpha_{3,1} = 4.201\),
which maximizes the growth rate for \(n = 3\). For example, comparing Figs.
4(a) and 5(a), we note that there is a considerable upshift in maximum
growth from normalized wavenumber \(k/k_0 = 31.5\) in Fig. 4(a) \((n = 1)\) to \(k/k_0 = 97.3\) in Fig. 5(a) \((n = 3)\), as the parameter \((\delta B/B_0)(\omega_{cb}/c_k)\) is increased
from 1.841 to 4.201. Figures 4 and 5 also illustrate the strong depend-
dence of growth rate on finite radial geometry. In particular, the plots
in Figs. 4(a) and 5(a) are presented for the case where the conducting wall is relatively close to the electron beam \( \left( \frac{R_b}{R_c} = 0.25, g_1 = 3.792 \times 10^{-2}, \right. \)

and \( g_2 = 1.314 \times 10^{-2} \), whereas the plots in Figs. 4(b) and 5(b) correspond to the case where the conducting wall is much further removed from the electron beam \( \left( \frac{R_b}{R_c} = 0.1, g_1 = 1.105 \times 10^{-3}, \right. \)

and \( g_2 = 3.704 \times 10^{-4} \). As \( \frac{R_b}{R_c} \) is decreased, we note that there is both an upshift in the value of \( k/k_0 \) corresponding to maximum growth as well as a significant reduction in growth rate. [Compare Figs. 4(a) and 4(b) or Figs. 5(a) and 5(b).] It is clear from the analytic results in Secs. IV.A and IV.B and the numerical results in Figs. 4 and 5, that there is a strong influence of radial geometry on the growth properties of the longitudinal wiggler free electron laser. Indeed, as expected from Figs. 2 and Eqs. (60) and (61), the closer the conducting wall \( (R_c) \) is positioned to the beam radius \( (R_b) \), the larger the instability growth rate becomes. Of course, this is associated with the fact that \( g_2 \) increases as \( \frac{R_b}{R_c} \) is increased [Fig. 2 and Eq. (54)].

Another striking feature of Figs. 4 and 5 is that the instability is relatively broadband. Even though \( \left( \frac{\delta B}{B_0} \right) \left( \frac{\omega_{cb}}{c k_0} \right) \) is chosen to maximize \( \text{Im} \omega \) for a particular value of \( n \), adjacent harmonics still have relatively strong growth. (See also the discussion at the end of Sec. IV.B).

**Cyclotron Maser Instability:** In the limiting case where \( \delta B = 0 \) and the applied magnetic field is given by the uniform value \( B_0 \hat{z}, \) only the \( n=0 \) term survives in Eq. (60) with \( J^2_0(0) = 1. \) The resulting dispersion relation applies to the cyclotron maser instability for the choice of solid electron beam equilibrium distribution in Eqs. (6) and (16). The dispersion relation (60) has been solved numerically for the growth rate \( \text{Im} \omega \) assuming \( \delta B = 0. \) Typical results are summarized in Fig. 6, where the normalized growth rate \( \text{Im} \omega / \omega_{cb} \) is plotted versus \( kR_b \) for the choice of parameters
\( \gamma_b = 2, \alpha_0 \ell = 3.83 \ (\ell = 1), \ \hat{V}_b/c = 0.1, \ V_b/c = 0.866 \) and \( \omega_{pb}/\omega_{cb} = 2.29 \times 10^{-2} \).

To illustrate the influence of finite radial geometry, we have chosen \( \hat{R}_b/R_c = 0.25 \) in Fig. 6(a) (corresponding to \( g_1 = 3.792 \times 10^{-2} \) and \( g_2 = 1.314 \times 10^{-2} \)) and \( \hat{R}_b/R_c = 0.1 \) in Fig. 6(b) (corresponding to \( g_1 = 1.105 \times 10^{-3} \) and \( g_2 = 3.704 \times 10^{-4} \)). As for the case of the longitudinal wiggler free electron laser (\( \delta B \neq 0 \)), it is clear from Fig. 6 that the relative positioning of the beam radius (\( \hat{R}_b \)) and the conducting wall radius (\( R_c \)) also has a large influence on the strength of the cyclotron maser instability. Indeed, the growth rate increases as \( \hat{R}_b/R_c \) is increased. [Compare Figs. 6(a) and 6(b).] As in Figs. 4 and 5, there is a concomitant upshift in \( k/k_0 \) corresponding to maximum growth as \( \hat{R}_b/R_c \) is decreased.
V. CONCLUSIONS

In this paper, we have investigated the influence of finite radial geometry on the longitudinal wiggler free electron laser instability. The analysis is carried out for a thin, tenuous electron beam propagating down the axis of a multiple-mirror (undulator) magnetic field (Sec. III). It is assumed that \( k^2 R_b^2 \ll 1 \) and that the amplifying radiation field has TE-mode polarization with perturbed field components \( (\delta E_\theta, \delta B_r, \delta B_z) \). A very important feature of the linear stability analysis (Secs. III and IV) is that the positioning of the beam radius relative to the conducting wall radius (as measured by \( R_b / R_c \), say) can have a large influence on the growth rate and detailed stability properties for perturbations about the choice of equilibrium distribution \( f_b^0(\chi, p) \) in Eq. (16).

Several points are noteworthy from the stability analysis in Sec. IV. First, for a given harmonic number \( n \), the characteristic maximum growth rate [Eq. (68)] is largest whenever the argument of \( J_n \) corresponds to the first zero of \( J_n'(x) = 0 \), i.e., when \( (\omega_{cb}/k_0 V_b)(\delta B/B_0) = \alpha_{n,1} \), where \( \alpha_{n,1} \) is the first zero of \( J_n'(x) = 0 \). Second, the growth rate scales as \( (\hat{V}_{lb}/c)^{2/3} n_b^{1/3} \), which can lead to substantial gain for the longitudinal wiggler free electron laser. Third, there is a strong dependence of stability properties on the positioning of the beam radius \( \hat{R}_b \) relative to the conducting wall radius \( R_c \). In particular, the growth rate \( \text{Im} \omega \) increases as \( \hat{R}_b / R_c \) is increased, and the detailed dependence of \( \text{Im} \omega \) on \( \hat{R}_b / R_c \) was examined numerically in Sec. IV. Another important feature of the results is that the instability is inherently broadband in the sense that many harmonics are unstable, even when \( (\omega_{cb}/k_0 V_b)(\delta B/B_0) \) is chosen to maximize emission for a particular value of \( n \).
Finally, also in Sec. IV, we investigated stability properties in the limiting case where $\delta B = 0$. This corresponds the cyclotron maser instability for perturbations about the solid electron beam equilibrium $f_b^0(x,p)$ specified by Eq. (16). The numerical results for $\delta B = 0$ also exhibited a strong dependence on radial geometry ($R_b/R_c$).
