Abstract: Silicon-vacancy (SiV) centers in diamond are bright sources of indistinguishable single photons. We report fabrication of nanowires coupled to single SiV by deterministic ion implantation, yielding greatly enhanced light coupling compared to SiV in bulk.

OCIS codes: 220.4241, 350.4238.

1. Introduction

The negatively-charged silicon-vacancy (SiV−) center in diamond consists of an interstitial Silicon atom between two vacancies in the carbon lattice (Fig.1-inset). It is a bright source of indistinguishable single photons with many potential applications in quantum information and communication [1]. Unfortunately, due to the high refraction index mismatch between diamond and air, color centers in diamond show low photon out-coupling. Fabricating nano-structures around these color centers can increase their optical coupling and enable quantum photonics applications. Here we report fabrication of monolithical nanowires coupled to single SiV− centres by deterministic Silicon ion implantation, and demonstrate produces an increase in photon count rate by at least a factor three with respect to defects in bulk diamond.

2. Methods

We performed a top-down procedure to produce a large array of nanowires [2] in a HPHT-diamond sample with electron-beam lithography and reactive-ion etching (RIE) techniques, Fig.1. Then we deterministically implanted Silicon ions in the nanowires by using focus ion beam technique (FIB) and finally obtained the creation of single SiV− centers embedded in the nanowires by annealing the sample. To characterize the SiV− we measured non-classical light emission using a home-built confocal microscope and a 50 : 50 fiber splitter. In correspondence to the lower dose implantations, we observed an antibunching dip (Fig.2.a), the signature of single photon emitters, as confirmed by fitting the data with the model discussed in [3]. The great benefits of coupling SiV− to the nanowires can be observed by the comparison between the count rate from an individual SiV− embedded in the nanowire Fig.2(c) and an ensemble of SiV− in a bulk crystal Fig.2(b). We measured the count rate of the photons emitted by the single SiV−

Fig. 1. Nanowires containing SiV color centers (a), Secondary electron emission image of a typical array of nanowires made for this experiment on a different diamond, (inset) atomic structure of a SiV color center. (b) Optical images of the nanowires array. (c) Confocal microscopy scan (15 × 15µm²) of the nanowires array after SiV creation. The first three rows of the array contains multiple SiV centers (~ 10), while other rows contains single or double SiV. The image clearly shows a correlation between the number of Si ions implanted and the number of SiV created.
inside the nanowire as function of the power of the excitation laser applied. As shown in Fig. 2(c) after a rise at low
pump powers ($P < P_{\text{sat}}$) the intensity of the counts saturates ($I = I_{\text{sat}}$) at high power ($P > P_{\text{sat}}$), as expected [4]. The
measured single SiV$^-$ saturation intensity is three times higher than for ensembles of SiV$^-$ in bulk, while thanks to
the nanowire effects, the single photon emitter get pumped at least five times more efficiently. We remark that these
results underestimate the nanowire coupling efficiencies, since we could not find single SiV$^-$ in the bulk diamond in
our sample and the comparison is made with a small ensemble of emitters.

3. Conclusions
We deterministically implanted single SiV$^-$ in nanowires monolithically created on diamond, by performing second
order correlation function measurement we demonstrated the single photon source nature of SiV$^-$ in the nanowires.
We also demonstrated an improvement in the coupling of the single SiV$^-$ due to presence of the nanowire, due to
the challenge of finding a single SiV$^-$ in the bulk the improvement is measured between single SiV$^-$ in the nanowires
and ensemble of SiV$^-$ in the bulk. Therefore nanowires are pumped at least five times more efficient than bulk colour
centre and allow at least three times higher single photon count rate. This result enables a new class of devices for
integrated photonic and quantum information process.
