We report on a search for new particles in the diphoton channel using a data sample of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV collected by the CDF II detector at the Fermilab Tevatron, with an integrated luminosity of 5.4 fb$^{-1}$. The diphoton invariant mass spectrum of the data agrees well with the standard model expectation. We set upper limits on the production cross section times branching ratio for the Randall-Sundrum graviton, as a function of diphoton mass. We subsequently derive lower limits on the graviton mass of 459 GeV/$c^2$ and 963 GeV/$c^2$, at the 95% confidence level, for coupling parameters ($k/M_{Pl}$) of 0.01 and 0.1, respectively.

The large disparity between the electroweak scale and the gravity scale (the Planck scale) is known as the hierarchy problem. In the Randall-Sundrum (RS) model [1], the hierarchy is generated by introducing one extra spatial dimension. The hierarchy is reproduced if the spectrum being a Kaluza-Klein (KK) tower of graviton states, the mass of which is generated from the Planck scale through a warp factor: 

$$M_{\pi} = M_{Pl} e^{-kr_c},$$  

where $\pi \sim$ TeV, $M_{Pl} = M_{Pl}/\sqrt{8\pi}$ is the reduced Planck scale, $k$ is the curvature scale of the extra dimension, and $r_c$ is the compactification radius of the extra dimension. The hierarchy is reproduced if $kr_c \approx 12$.

The compactification of the extra dimension gives rise to a Kaluza-Klein (KK) tower of graviton states, the mass spectrum being 

$$m_n = x_n (k/M_{Pl}) \Lambda_{\pi},$$  

where $x_n$ is the nth root of the first-order Bessel function, and the states couple with strength $1/\Lambda_{\pi}$. Two parameters determine graviton couplings and widths: the constant $k/M_{Pl}$ and the mass of the first KK graviton excitation $m_1$. We examine values in the range $0.01 \leq k/M_{Pl} \leq 0.1$ since the values of $k$ must be large enough to be consistent with the apparent weakness of gravity, but small enough to prevent the theory from becoming nonperturbative [2]. The graviton decay modes are expected to produce distinctive final states: the diphoton state from s wave decays and the dilepton state from p wave decays. The spin-2 nature of the graviton favors a search in the diphoton channel, where the branching ratio (4%) is twice that of any single dilepton channel (2%) [3].

In this paper, we report on a search for the first KK graviton excitation of the RS model in the diphoton decay channel. We use 5.4 fb$^{-1}$ of integrated luminosity collected by the CDF II detector at the Fermilab Tevatron using $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV between February 2002 and June 2009. Existing lower mass limits on RS gravitons from the previous CDF analysis using data corresponding to 1.2 fb$^{-1}$ of integrated luminosity in the diphoton channel are 230 GeV/$c^2$ and 850 GeV/$c^2$ for $k/M_{Pl} = 0.01$ and 0.1, respectively, at the 95% confidence level (C.L.) [4]. The most recent limits from the D0 Collaboration are from a combined diphoton and dielectron search using data corresponding to 5.4 fb$^{-1}$ of integrated luminosity, with limits of 560 GeV/$c^2$ and 1050 GeV/$c^2$ for $k/M_{Pl} = 0.01$ and 0.1, respectively [5].

The CDF II detector has a cylindrical geometry with forward-backward and azimuthal symmetry. It consists of a tracking system in a 1.4 T magnetic field, coaxial with the beam, surrounded by calorimeters and muon detection chambers [6]. The tracking system consists of a silicon tracker (SVX-II) [7] and an open cell drift chamber (COT) [8]. COT covers the pseudorapidity range $|\eta| < 1.0$ [6], and the silicon detector extends the tracking coverage to $|\eta| < 2.0$. The central and plug calorimeters [9] are sampling calorimeters that surround the COT and cover the ranges $|\eta| < 1.1$ and $1.2 < |\eta| < 3.6$, respectively. The calorimeters, consisting of electromagnetic (EM) and hadronic layers arranged in a projective geometry, allow measurement of the “transverse energy” $E_T = E \sin(\theta)$ [6]. At the approximate electromagnetic shower maximum, the EM calorimeters contain fine-grained detectors [10] that measure the shower shape and centroid position in the two dimensions transverse to the shower development. Surrounding these detectors is a system of muon detectors [11]. A three-level real-time event-selection system (trigger) filters events.

The events used in this analysis are selected by at least one of four triggers. Two of them require two clusters of electromagnetic energy: one requires both clusters to have transverse energy $E_T > 12$ GeV and be isolated in the calorimeter; the other requires the two clusters to have $E_T > 18$ GeV but makes no isolation requirement. To ensure very high trigger efficiency for large $E_T$ photons, events are also accepted from two single photon triggers with no isolation requirements. One requires $E_T > 50$ GeV, while the other requires $E_T > 70$ GeV with relaxed requirements.

DOI: 10.1103/PhysRevD.83.011102  PACS numbers: 12.38.Qk, 13.85.Qk, 13.85.Rm
on the hadronic energy associated with clusters. The combination of these triggers is effectively 100% efficient for the kinematic region used in this search for diphoton events with an invariant mass above 100 GeV/$c^2$.

In the selected sample, each event is required to have at least two photon candidates. If there are more than two photon candidates, only the two photons with the highest $E_T$ are used. Both photons are required to be in the fiducial region of the central calorimeter (approximately in the region $|\eta| < 1.04$). Each of the two photons is required to have an energy cluster predominantly in the electromagnetic calorimeter portion with $E_T > 15$ GeV, and the photon pair is required to have a reconstructed diphoton invariant mass greater than 30 GeV/$c^2$. Both clusters are required to be in the fiducial region of the shower maximum detectors and to pass the following photon identification criteria: transverse shower profiles must be consistent with a single photon, additional transverse energy in the calorimeter in a cone of angular radius $R = \sqrt{(\Delta \phi)^2 + (\Delta \eta)^2} = 0.4$ [6] around the photon candidate must be less than 2 GeV, and the scalar sum of the transverse momentum $p_T$ of the tracks in the same cone must be less than 2 GeV/$c$. Photons are required to have isolated energy clusters in the shower maximum detector.

The selected data consist of 47 920 events. The diphoton invariant mass distribution for these events, histogrammed in bins equivalent to the mass resolution (approximately by 0.13$\sqrt{m}$ $\oplus$ 0.02$m$ GeV/$c^2$ [9], where $m$ is the diphoton mass in GeV/$c^2$) is shown in Fig. 1. The highest mass pair occurs at 603 GeV/$c^2$.

The expected number of RS graviton events, as a function of graviton mass, is estimated using the PYTHIA6.226 event generator [12], with CTEQ5L parton distribution functions (PDFs) [13], and processed by the GEANT3-based CDF II detector simulation [14]. The photon selection efficiency determined from the simulation is multiplied by a correction factor which is derived as the ratio of the measured and simulated detector response to electrons from Z boson decays, since a pure sample of reconstructed photons is not available, and the characteristics of energy deposited in the calorimeter by electrons are almost identical to those of photons. The $Z^0 \rightarrow e^+ e^-$ sample is also used to calibrate the electromagnetic energy scale. The diphoton energy scale in data and Monte Carlo samples is corrected by tuning the $Z^0 \rightarrow e^+ e^-$ mass peak to the world average value [15]. We also correct for effects introduced by multiple interactions in the same beam crossing. The combined acceptance and selection efficiency for RS diphoton events increases from 0.12 ± 0.01(stat) ± 0.01(syst) for gravitons of mass 200 GeV/$c^2$ to 0.33 ± 0.01(stat) ± 0.03(syst) for gravitons of mass 1100 GeV/$c^2$. The largest systematic uncertainties on the expected number of graviton events arise from the luminosity measurement (6%) and the uncertainty associated with the initial and final state radiation (ISR/FSR). The uncertainty on the efficiency resulting from ISR/FSR is estimated to decrease from 8% for gravitons of mass 200 GeV/$c^2$ to 4% for gravitons of mass 1100 GeV/$c^2$ by varying the parton shower parameters in PYTHIA.

There are two significant background components in the diphoton data sample. The first is SM diphoton production. We estimate the shape of this background with the DIPHOX next-to-leading-order (NLO) Monte Carlo [16] calculation. This program calculates the cross section for diphoton production in the hadronic collisions as a function of mass. Previous studies show that DIPHOX describes the shape of the SM diphoton invariant mass spectrum well in the range used for this analysis (diphoton invariant mass above 100 GeV/$c^2$) [17].

FIG. 1. The diphoton invariant mass distribution of events, histogrammed in bins of approximately one unit of calorimeter mass resolution. The width of the horizontal bar represents the bin size. The bin size is $2.4(10.4)$ GeV/$c^2$ at $m(\gamma\gamma) = 100(500)$ GeV/$c^2$. 

The mass distribution of the DIPHOX calculation is fitted to a product of a polynomial and the sum of five exponential distributions in the range 30 GeV/$c^2$ to 1.3 TeV/$c^2$. The fitted invariant mass spectrum is then multiplied by an efficiency function derived from a SM diphoton sample generated by PYTHIA and processed through the full detector simulation. The second background component, negligible except at the lowest masses, arises from the misidentification of one or two jets as photons. The invariant mass shape of this background is parametrized with a product of a polynomial and the sum of two exponentials. This functional form is justified, but not fixed, by a study using a sample of photonlike jets obtained by loosening the photon selection criteria (transverse shower profile and isolation requirements) for both photon candidates, then removing the events which pass all the signal selection requirements.

To find the most accurate description of the background invariant mass for setting limits, we fit a functional form which is a sum of the DIPHOX shape and the photonlike jet shape to the invariant mass spectrum of the data. All the parameters in the functional form for the photonlike jets

PHYSICAL REVIEW D 83, 011102(R) (2011) RAPID COMMUNICATIONS
and the normalization of the SM diphoton background are allowed to vary in the fit. We fit the invariant mass spectrum in the range \(m_{\gamma\gamma} > 100 \text{ GeV}/c^2\) since RS gravitons have been excluded at the 95% C.L. in the lower mass region by previous searches.

Figure 2 shows the observed mass spectrum with the fitted total background overlaid. The best fit SM background normalization is consistent with the DIPHOX calculation. The contribution of jets faking photons is highly suppressed at high diphoton masses since we restrict the amount of energy allowed in the isolation cone of each photon candidate. Also shown in the figure is the systematic uncertainty on the total background, which is approximately 20%. The systematic uncertainty arises predominantly from the choice of the \(Q^2\) scales used in the DIPHOX calculation for low mass diphoton events and from the choice of the PDFs for high mass diphoton events. The systematic uncertainties are taken to be completely correlated across all mass bins. Correlations in the systematic uncertainties between signal and background are taken into account.

A model-independent search for an excess over SM predictions is performed, following the procedure outlined in [18]. The search is optimized for a narrow resonance, but still retains sensitivity to other signals which would produce an excess over SM predictions. We scan a mass window over the mass region 100–700 GeV/c^2. The mass window is approximately the width a narrow resonance would have if observed in the CDF detector. The probability that the background could give rise to the observed number of events in the mass window, referred to as the \(p\) value, is calculated using Poisson statistics.

The uncertainty on the background estimate is treated as a nuisance parameter with a Gaussian distribution. The lowest \(p\) value observed is 0.016 at 198 GeV/c^2. The method is repeated for 200,000 simulated experiments produced using the background prediction. Approximately 60% of the simulated experiments give a minimum \(p\) value equal to or less than 0.016. Therefore we conclude that the observed diphoton invariant mass spectrum is consistent with the background prediction.

We use the \(CL_s\) limit-setting technique [19] to set the upper limits for the production cross section of RS gravitons times the branching fraction into the \(\gamma\gamma\) final state using the diphoton mass spectrum. In this method, the data are compared against two models at a time. One is the null hypothesis \(H_0\), which asserts that the SM diphoton production and misidentified jets describe the data, while the other is the signal at a fixed mass plus background hypothesis \(H_1\). The probability ratio

\[
CL_s = \frac{P_{H_1}(\Delta \chi^2 \approx \Delta \chi^2_{\text{obs}})}{P_{H_0}(\Delta \chi^2 \approx \Delta \chi^2_{\text{obs}})}
\]

is used to set the limits. The numerator and denominator are calculated by generating simulated experiments assuming hypothesis \(H_1\) and hypothesis \(H_0\), respectively, and taking into account systematic uncertainties on signal and background predictions. \(\Delta \chi^2_{\text{obs}}\) is the difference in the logarithm likelihood values calculated by comparing the data in the simulated (real) experiment against the prediction of \(H_0\) or \(H_1\). The 95% C.L. upper limit corresponds to the cross section which gives \(CL_s = 0.05\).

The result is shown in Fig. 3, as a function of graviton mass, along with the theoretical cross section times branching ratio for RS gravitons with \(k/M_P\) set to 0.1, 0.07, 0.05, 0.025, and 0.01. The leading-order graviton production cross section calculated by PYTHIA [12] is

![Graph showing diphoton invariant mass spectrum](image1)

**FIG. 2 (color online).** The diphoton invariant mass spectrum with the fitted total background overlaid. The points are the data. The width of the horizontal bar represents the bin size which is fixed at 5 GeV/c^2. The dotted line shows the contribution from events where at least one selected photon is from a misidentified jet, and the solid line shows this background plus the DIPHOX SM diphoton distribution. For clarity, the SM background is not shown in the figure since it is almost indistinguishable from the total background. The gray band shows the uncertainty on the total background.

**FIG. 3 (color online).** The 95% C.L. upper limit on the production cross section times branching fraction of an RS model graviton decaying to diphotons \([\sigma \times \text{Br}(G \rightarrow \gamma\gamma)]\) as a function of graviton mass. Also shown are the predicted \((\sigma \times \text{Br})\) curves for \(k/M_P = 0.01, 0.07, 0.05,\) and 0.1 [20].

011102-6
masses. From the limit on conservative limits at low masses and optimistic limits at high graviton as a function of the parameter bounds are derived for the first excited state of the RS K$_a$ mass-independent factor of 1.3, which leads to conservative limits at low masses and optimistic limits at high masses. From the limit on $\sigma \times \text{Br}(G \rightarrow \gamma\gamma)$, lower mass bounds are derived for the first excited state of the RS graviton as a function of the parameter $k/M_{Pl}$. The 95% C.L., excluded region in the $k/M_{Pl}$ and graviton mass plane is displayed in Fig. 4, with the mass limits summarized in Table I.

In conclusion, we have searched for evidence of an anomalous peak in the diphoton mass spectrum using data corresponding to an integrated luminosity of 5.4 fb$^{-1}$ collected by the CDF II detector at the Fermilab Tevatron. We find no evidence of new physics. We evaluate one model of hypothetical new diphoton production and exclude RS gravitons below masses ranging from 459 to 963 GeV/c$^2$, for a coupling parameter $k/M_{Pl}$ of 0.01 to 0.1, at the 95% C.L. This results in a significant improvement, at high mass, over the previous best available limit in the diphoton state from CDF. The limits are less stringent than those from D0 using the same integrated luminosity [5]. Some contributing factors include the omission of the dielectron data and the use of mass-dependent K factors in this CDF analysis.

We thank the Fermilab staff and the technical staffs of the participating institutions for their vital contributions.
