Abstract

Endothelial cells represent an important anatomic and functional barrier separating circulating cells and molecules of the vascular space, from the stroma and tissue-specific cells of solid organs. As such endothelial cells play a critical role in inflammation by sensing danger signals, and subsequently initiating the expression of cellular adhesion factors and the secretion of inflammatory cytokines [1,2]. During an infection or sterile injury, pathogens and damaged host cells release danger signals such as lipopolysaccharides (LPS), peptidoglycans (PGN), high-mobility group protein-1 (HMGB1), and double stranded DNA (dsDNA) into circulation [3,4,5,6,7,8]. Many of these danger signals have been shown to activate innate immune and inflammatory responses in endothelial cells [9,10,11,12]. However, little is known about the direct effects of dsDNA on the vascular endothelium.

DNA has recently emerged as a potent activator of the innate immune system. Mammalian cells are exposed to dsDNA that is released from damaged host cells during tissue injury, or introduced by DNA viruses and intracellular bacteria during infection [13,14,15,16,17]. Many cytosolic receptors including Z-DNA binding protein 1 (ZBP1) and gamma-interferon-inducible protein 16 (IFI16) have been identified for sensing dsDNA [17,18]. Signaling through these receptors triggers the activation of kinases such as TBK1 and Ikk, and the downstream phosphorylation of transcription factors IRF3 and NFκB [15]. Numerous investigations have revealed that dsDNA stimulation elicits a robust antiviral and inflammatory response in innate immune cells [15,19,20,21]. Dendritic cells have been shown to secrete large amounts of interferon α/β, as well as chemokines IP10 and CCL5, in response to dsDNA [15]. In macrophages, dsDNA stimulation has been shown to trigger the robust production of proinflammatory cytokines IL1β and IL18 [20]. A recent study revealed that during sterile drug-induced liver injury, sinusoidal endothelial cells can also sense dsDNA from damaged hepatocytes and initiate an acute inflammatory response, however the mechanism remains unknown [14]. While endothelial cells are well known to respond to indirect stimulation by cytokines [22], their role as primary responders to direct stimulation by danger signals such as dsDNA is just recently emerging. The purpose of this study was to investigate the inflammatory response of endothelial cells to direct dsDNA treatment.

In this work we show for the first time that endothelial cells exposed to dsDNA trigger the activation of NFκB and MAPK pathways, including JNK and p38. This leads to increased expression of ICAM1, VCAM1 and E-selectin, and results in functional leukocyte adhesion. We demonstrate that endothelial sensing of dsDNA induces robust expression and secretion of inflammatory cytokines—an acute inflammatory response that is critical for host defense and tissue repair.
TNFα, which mediates sustained secondary activation of the endothelium. Mice deficient in the TNF receptor are unable to mount an acute inflammatory response to DNA. Furthermore, both NFκB and IRF3 are required for the production of the TNFα in response to dsDNA. This study suggests a possible role for endothelial cells in mediating dsDNA-induced inflammatory responses, and implicates their importance in establishing an acute inflammatory response to systemic infection or sterile injury such as ischemia-reperfusion injury, where pathogen or host dsDNA may serve as a danger signal.

**Results**

**Endothelial activation and leukocyte adhesion is triggered by dsDNA stimulation**

Endothelial activation is an early event through which pathogen-associated molecular patterns induce inflammation during infection and tissue injury. Recent studies have established the role of dsDNA as a potent activator of the innate immune system [23]. For evaluating endothelial activation in response to DNA stimulation, we treated endothelial cells with synthetic B-form Poly(dA-dT):Poly(dA-dT) (hereafter referred to as dsDNA), a known intracellular DNA ligand [15]. dsDNA treatment resulted in increased expression of endothelial adhesion molecules ICAM1, VCAM1, and E-selectin (Figure 1a). The greatest increase in gene expression was observed for VCAM1 (Figure 1a). Adhesion molecules play a central role in leukocyte recruitment by regulating their attachment to the endothelium. To determine if dsDNA stimulation results in increased leukocyte adhesion, confluent monolayers of endothelial cells were treated with dsDNA, and then co-cultured with cell membrane dye-labeled peripheral blood leukocytes. TNFα stimulated endothelial cells were used as a positive control for measuring leukocyte adhesion under inflammatory conditions. dsDNA stimulation of RHMEC lead to significantly enhanced binding of leukocytes (3.5 fold), in comparison to Lipofectamine treated cells (Figure 1b). Our results indicate that dsDNA acts as a potent activator of the endothelium by increasing the expression of adhesion molecules and directly enhancing leukocyte adhesion.

**dsDNA-induced activation of NFκB and MAPK pathways**

NFκB and MAPK pathways are known to play an important role in regulating the expression of endothelial adhesion molecules [22]. Given that dsDNA stimulation leads to increased expression of adhesion molecules, we examined the activation of NFκB and MAPK pathways in response to dsDNA. For evaluating NFκB activation, a reporter clone of endothelial cells that synthesizes GFP in response to NFκB activation was utilized. dsDNA stimulation of NFκB endothelial cell reporters resulted in elevated levels of GFP compared to Lipofectamine stimulated cells, suggesting NFκB activation by dsDNA (Figure 2a). A nuclear ELISA for NFκB activation further confirmed that dsDNA induced dose-dependent activation of NFκB in endothelial cells after 6 hours of stimulation (Figure 2b). For evaluating MAPK activation, phosphorlated protein levels of JNK, p38, and ERK1/2 were measured in endothelial cells stimulated with dsDNA for 6 hours. Endothelial cells treated with dsDNA showed elevated levels of phosphorlated JNK and p38 in comparison to Lipofectamine treated cells (Figure 2c). However, levels of phosphorlated ERK1/2 were similar in both dsDNA stimulated and control cells (Figure 2c).

These results suggest that dsDNA induces the activation of NFκB, JNK and p38 signaling pathways in endothelial cells, but not ERK1/2.

**Regulation of adhesion molecule expression by modulation of NFκB and MAPK pathways**

We next sought to determine whether dsDNA induced activation of NFκB, JNK, and p38 pathways was required for increased expression of endothelial adhesion molecules. Endothelial cells were treated with dsDNA for 4 hours in the presence or absence of PDTC, SP600125, or SB202190, known inhibitors of NFκB [24], JNK [25], and p38 MAPK [26] pathways, respectively. Inhibition of NFκB, JNK, and p38 resulted in significantly reduced expression of ICAM1, VCAM1 and E-selectin, suggesting that all three signaling pathways are involved in dsDNA stimulated endothelial activation (Figure 2d). Inhibition of NFκB was most potent at reducing expression of these adhesion molecules (Figure 2d). Given that JNK and p38 MAPK are known activators of the AP1 family of transcription factors [27], our results suggest that transcription factors AP1 and NFκB may be required for dsDNA-induced endothelial activation.

NFκB and IRF3 are required for dsDNA-induced TNFα production

TNFα is an important mediator of inflammation, as it acts on vascular endothelial cells to promote expression of adhesion molecules [26]. Having demonstrated mechanistically how direct stimulation of endothelial cells with dsDNA results in the expression of adhesion molecules, we next sought to investigate whether dsDNA induced TNFα production. dsDNA stimulation of endothelial cells resulted in upregulation of TNFα expression and robust secretion of TNFα into the culture supernatant, compared to Lipofectamine stimulation (Figure 3a,b). To determine the transcription factors necessary for TNFα production in

![Figure 1. dsDNA induced activation of the endothelium.](image-url)
response to dsDNA, we used transgenic knockout mouse embryonic fibroblasts (MEFs). Wildtype MEFs (WT) stimulated with dsDNA induced significant TNFα secretion after 24 hours (Figure 4c). Conversely, MEFs deficient in TBK1 and IKKε (TBK1/IKKε DKO), kinases necessary for IRF3 activation, failed to produce TNFα (Figure 3c). Similarly, dsDNA-stimulated MEFs deficient in IKKα and IKKβ (IKKα/IKKβ DKO), kinases essential for NFκB activation, also failed to produce TNFα (Figure 3c). To determine whether dsDNA-induced activation of NFκB, JNK, and p38 MAPK pathways was required for TNFα production, endothelial cells were treated with dsDNA for 24 hours in the presence or absence of known inhibitors of NFκB, JNK and p38 MAPK pathways. Inhibition of NFκB, JNK, and p38 MAPK significantly reduced TNFα production, although the reduction was more pronounced for NFκB and JNK inhibitors in comparison to p38 MAPK inhibitor. These results suggest that all three signaling pathways are involved in dsDNA stimulated TNFα production (Figure 3d). Together, these data suggest that dsDNA-induced TNFα secretion is dependent on both IRF3 and NFκB activation, and JNK signaling pathways.

We then sought to determine whether dsDNA-induced TNFα influences overall endothelial activation, since the expression of many adhesion molecules, such as VCAM1, is indirectly promoted by proinflammatory cytokines [22]. Using cycloheximide, a classic inhibitor of protein translation, we first clarified what portion of dsDNA-induced VCAM1 expression is from direct sensing of dsDNA and what part is from secondary indirect activation, requiring de novo protein synthesis. After 4 hours of dsDNA stimulation, VCAM1 expression, in the presence or absence of cycloheximide, was approximately equal (Figure 3e). However, after 12 hours of dsDNA stimulation, VCAM1 expression in the

doi:10.1371/journal.pone.0019910.g003
The endothelium exists at the interface between the vascular and tissue compartments, and is responsible for communicating danger signals during infection or sterile injury. Recently, dsDNA from pathogens and dying host cells was found to be a potent danger signal, capable of activating immune and inflammatory responses in many types of innate immune cells [13,15,16,17]. In the current study we explore the consequences of directly stimulating endothelial cells with dsDNA. We show that dsDNA stimulation leads to expression and secretion of TNFα, as well as upregulation of surface adhesion molecules that facilitate leukocyte recruitment. These responses depend on activation of upstream MAP kinases JNK and p38, as well as activation of transcription factor NFκB. Furthermore, we provide evidence demonstrating that IRF3 and NFκB are both required for dsDNA-induced TNFα secretion, and show that TNFα is required for sustained secondary activation of the vascular endothelium.

The cellular response to dsDNA can be divided into two categories, a proinflammatory component mediated by the cytokines such as TNFα and IL1β, and an antiviral component mediated by type I interferons [20]. While the molecular pathways of the interferon response to dsDNA have been intensively investigated, the inflammatory arm has received comparatively less attention. TNFα and IL1β are arguably the most potent cytokines involved in inducing inflammation. They play a specific role in endothelial activation by inducing expression of cell surface adhesion molecules [22]. Investigations of dsDNA-induced inflammation have largely focused on the secretion of IL1β [20,29]. Stimulation of cells with dsDNA triggers the robust secretion of IL1β by activating the inflammasome through the cytosolic DNA sensor absent in melanoma 2 (AIM2) and the endosomal DNA sensor TLR9, both of which are expressed in a cell type specific manner [29,30]. These sensors bind dsDNA, and associate with inflammasome adaptor molecules for caspase-1 mediated secretion of IL1β, which can indirectly stimulate the endothelium [14,29]. While the molecular details of dsDNA-induced IL1β secretion have been extensively investigated, the mechanism by which dsDNA triggers secretion of TNFα and its role in dsDNA-mediated inflammation remains relatively unexplored.

In this study, we focus on dsDNA-induced NFκB activation and TNFα secretion, and explore its ability to initiate and amplify a proinflammatory response in endothelial cells. We chose this cell type because of its unique location at the interface between tissue and vascular compartments, its likelihood of being exposed to danger signals, and because of its important functional role in recruiting immune cells to areas of injury. Endothelial cells are known to respond to indirect stimulation by proinflammatory cytokines commonly secreted in response to dsDNA [22], but their ability to directly sense dsDNA has not been examined. A recent study showed that free dsDNA released from apoptotic cells can directly stimulate endothelial cells to secrete IL1β and IL18 [14], however the mechanism remains unknown, and the subsequent activation of the endothelium unexplored.

dsDNA-mediated acute inflammation is dependent on TNFα

To evaluate the in vivo role of TNFα in acute inflammation triggered by dsDNA, we developed an in vivo model of dsDNA-induced inflammation. We injected complexed-DNA, as well as complexed-DNAse digested DNA, intraperitoneally (i.p.) into mice. After 16 hours, mice injected with dsDNA had abundant neutrophils in their abdominal cavities (Figure 4a), indicated by the staining of peritoneal lavage cells with the neutrophil marker Ly-6G. However, mice injected with DNAse digested DNA had minimal neutrophil infiltration (Figure 4a), in agreement with prior reports suggesting that DNAse digestion renders DNA inert to innate immune system. Mice deficient in the TNFα receptor (TNFR1−/−) also had significantly reduced neutrophil accumulation when injected with dsDNA, compared to abundant neutrophils in TNFR1+/+ mice (Figure 4b). Taken together, these results demonstrate that detection of dsDNA triggers acute inflammation dependent on TNFα signaling.

Discussion

The endothelium exists at the interface between the vascular and tissue compartments, and is responsible for communicating danger signals during infection or sterile injury. Recently, dsDNA from pathogens and dying host cells was found to be a potent danger signal, capable of activating immune and inflammatory responses in many types of innate immune cells [13,15,16,17]. In the current study we explore the consequences of directly stimulating endothelial cells with dsDNA. We show that dsDNA stimulation leads to expression and secretion of TNFα, as well as upregulation of surface adhesion molecules that facilitate leukocyte recruitment. These responses depend on activation of upstream MAP kinases JNK and p38, as well as activation of transcription factor NFκB. Furthermore, we provide evidence demonstrating that IRF3 and NFκB are both required for dsDNA-induced TNFα secretion, and show that TNFα is required for sustained secondary activation of the vascular endothelium.

The cellular response to dsDNA can be divided into two categories, a proinflammatory component mediated by the cytokines such as TNFα and IL1β, and an antiviral component mediated by type I interferons [20]. While the molecular pathways of the interferon response to dsDNA have been intensively investigated, the inflammatory arm has received comparatively less attention. TNFα and IL1β are arguably the most potent cytokines involved in inducing inflammation. They play a specific role in endothelial activation by inducing expression of cell surface adhesion molecules [22]. Investigations of dsDNA-induced inflammation have largely focused on the secretion of IL1β [20,29]. Stimulation of cells with dsDNA triggers the robust secretion of IL1β by activating the inflammasome through the cytosolic DNA sensor absent in melanoma 2 (AIM2) and the endosomal DNA sensor TLR9, both of which are expressed in a cell type specific manner [29,30]. These sensors bind dsDNA, and associate with inflammasome adaptor molecules for caspase-1 mediated secretion of IL1β, which can indirectly stimulate the endothelium [14,29]. While the molecular details of dsDNA-induced IL1β secretion have been extensively investigated, the mechanism by which dsDNA triggers secretion of TNFα and its role in dsDNA-mediated inflammation remains relatively unexplored.

In this study, we focus on dsDNA-induced NFκB activation and TNFα secretion, and explore its ability to initiate and amplify a proinflammatory response in endothelial cells. We chose this cell type because of its unique location at the interface between tissue and vascular compartments, its likelihood of being exposed to danger signals, and because of its important functional role in recruiting immune cells to areas of injury. Endothelial cells are known to respond to indirect stimulation by proinflammatory cytokines commonly secreted in response to dsDNA [22], but their ability to directly sense dsDNA has not been examined. A recent study showed that free dsDNA released from apoptotic cells can directly stimulate endothelial cells to secrete IL1β and IL18 [14], however the mechanism remains unknown, and the subsequent activation of the endothelium unexplored.
In this report, we established that dsDNA sensing by endothelial cells leads to potent expression and secretion of TNFα. This is in agreement with prior studies using other cell types, which showed that undigested mammalian dsDNA induced TNFα secretion in macrophages [31], and enhanced expression of TNFα in dsDNA stimulated hepatocytes [32]. We also showed that dsDNA-mediated TNFα secretion was abrogated in MEFs deficient in kinases necessary for NFκB and IRF3 activation suggesting that both transcription factors are necessary for the response, which is analogous to LPS-induced TNFα secretion [33,34]. Finally, we discovered TNFα as an essential mediator of dsDNA-induced acute inflammation, as mice lacking the TNF receptor exhibited a dramatic reduction in the inflammatory response to dsDNA stimulation in vivo. Although, it is important to note that eliminating the TNFα signaling did not completely abrogate the inflammatory response. Our studies did not resolve if the minor response observed in mice lacking the TNF receptor was due to direct induction of adhesion molecules by dsDNA or indirect contribution of other cytokine(s). Dissecting the relative contributions of direct and indirect endothelial cell activation to this response, establishing the cellular source of TNFα, and determining possible involvement of other cytokine(s) will require further investigation.

Results from this study may have important implications in host defense and sterile injury. Direct sensing of dsDNA by the vascular endothelium suggests that endothelial cells may play an active role in mounting immune responses to systemic infection. In particular, DNA viruses such as cytomegalovirus (CMV), Epstein-Barr virus (EBV) and Herpes simplex virus-1 (HSV1) have been shown to infect the vascular endothelium resulting in dysfunction and injury that plays an important role in viral pathogenesis [10,35,36]. Endothelial cells may also be exposed to host dsDNA when cells die in vivo in the absence of infection due to sterile injury. During an ischemic injury, such as a myocardial infarction, damaged myocytes release genomic dsDNA locally into circulation [37] where it can stimulate a potent inflammatory response in endothelial cells, including a rapid influx of neutrophils to the site of injury. This sterile inflammation may contribute to the pathogenesis of acute ischemic injuries, as well as other forms of sterile injury including drug-induced toxicity. More studies are needed to better understand the precise role dsDNA plays in activating the endothelium during infection or sterile injury.

Another area of relevance for endothelial dsDNA-sensing is the response to gene therapy. The endothelium represents an attractive target for gene therapy because of its accessibility by the tissue compartment of solid organs. However, designing gene therapy vectors that minimize endothelial cell activation has proven to be challenging [38]. This could be related to the fact that gene therapy vectors are often derived from dsDNA-viruses, complexed plasmid dsDNA, or naked dsDNA, which can induce innate immune and inflammatory responses. Manipulating the immune and inflammatory responses of dsDNA-stimulated endothelial cells using knowledge of the underlying molecular machinery represents a unique opportunity to overcome these challenges.

Materials and Methods

Materials

Dulbecco’s Modified Eagle Medium (DMEM), penicillin-streptomycin, and fetal bovine serum (FBS) were acquired from Invitrogen Life Technologies (Carlsbad, CA). Pyrrolidine dithiocarbamate (PDTC), SP600125, SB202190 were obtained from Tocris bioscience (Ellisville, MO). Synthetic polydeoxynucleotide, poly(dA-dT):poly(dA-dT) dsDNA, was purchased from Amersham Biosciences. MCDB-131-complete medium was obtained from VEC Technologies (Rensselaer, NY). Rat tumor necrosis factor-α (TNFα) was purchased from R&D Systems (Minneapolis, MN).

Transfection of cells

Primary rat heart microvessel endothelial cells were acquired from VEC Technologies and maintained in MCDB-131 medium supplemented with 10% FBS, 10 ng/ml EGF, 1 µg/ml hydrocortisone, 200 µg/ml EndoGRO, 90 µg/ml heparin, and 1% antimycotic solution. For transfections, endothelial cells were switched to DMEM media supplemented with 10% FBS, and 2% penicillin-streptomycin. dsDNA transfections were performed by using Lipofectamine LTX [Invitrogen] at a ratio of 1.5:1 (volume/weight) with dsDNA as per manufacturer’s protocol. For experiments involving the use of inhibitors, cells were pretreated with PDTC (5 µg/ml), SP600125 (20 µM), or SB202190 (10 µM) in DMEM for 1 h before dsDNA stimulation and during stimulation. For some experiments, endothelial cells were pretreated with a TNFα neutralizing antibody (2 µg/ml; R&D Systems), or cyclohexamide (20 µg/ml; Sigma Aldrich) for 1 hour before dsDNA stimulation and during stimulation.

Mouse embryonic fibroblasts (MEFs) were maintained in DMEM media supplemented with 10% FBS, and 2% penicillin-streptomycin. dsDNA transfections were performed as described above. Unless otherwise noted, all experiments were done three times.

Real time polymerase chain reaction

RNA was extracted from cells using nucleosipin RNA II kit (Macherey-Nagel Inc., Bethlehem, PA) according to the manufacturer’s instructions. Quantitative Reverse Transcription PCR was performed using the Superscript III two-Step qRT-PCR kit purchased from Invitrogen (Carlsbad, CA). 500 ng of cellular RNA was reverse transcribed according to the manufacturer’s directions. Real-time quantitative PCR was performed using the Stratagene (La Jolla, CA) MX5000P QPCR system. Each reaction was carried out with 10 ng cDNA and 0.6 µM primers. During amplification, the cycling temperatures were 95°C for 15 seconds, 60°C for 1 minute and 72°C for 30 seconds. The following primers were used for amplifying DNA: E-Selectin forward primer: CAACACATCCCTGACGTGTGC; E-Selectin reverse primer: AGCTGAAGGAGCAGGATGA; ICAM-1 forward primer: CACGCTGGCAGCAGCA; ICAM-1 reverse primer: GACCGTGCTAGTGACATG; E-Selectin forward primer: GTCTGTGCCTCAGCCTCTTC; TNFα forward primer: CCTCTTGCGAAGACGAAAC; ICAM-1 forward primer: CAACACATCCTCGAGTGTT; and TNFα reverse primer: CGTTCGTCAGCTGCAAGTC; TNFα forward primer: TGAAGGGCCTACATCCACAC; TNFα reverse primer: CCTCTTGCGAAGACGAAAC; and mouse TNFα respectively, that was secreted as measured by ELISA (R&D Systems) to determine the amount of rat TNFα and mouse TNFα, which can be used to calculate fold change.

TFNα ELISA

Supernatants from endothelial cells and MEFs were used to determine the amount of rat TNFα and mouse TNFα, respectively, that was secreted as measured by ELISA (R&D Systems) according to the manufacturer’s protocol.

Fluorescent Microscopy

Images were acquired using a Zeiss 200 M microscope (Carl Zeiss Inc., Thornwood, NY). The fluorescence images were
Leukocyte adhesion experiments

Peripheral blood leukocytes were purified from heparinized peripheral blood of rat using Histopaque density gradient (Sigma) according to manufacturer’s instructions. Leukocytes were labeled with CM-DiI (25 μg/ml) at 37°C for 10 minutes and then added to endothelial cells that were stimulated with dsDNA (2 μg/ml) or TNFα (10 ng/ml) for 12 hours. Leukocytes were allowed to adhere for 60 minutes at 37°C and then washed 3 times with PBS for removing nonadhered cells. Fluoresced images were captured and analyzed using Image J software (National Institute of Health, Bethesda, MD) to estimate the degree of leukocyte adhesion to endothelial cells.

Construction of NFκB reporter clone of endothelial cells

NFκB reporter plasmid consisted of multiple response elements upstream of destabilized green fluorescent protein gene that encodes for d2EGFP reporter protein [39]. The details describing the construction of NFκB reporter clone of endothelial cells are reported elsewhere [40]. Briefly, endothelial cells (2.5 million) were electroporated with the NFκB reporter plasmid (10 μg) using a BTX Electro Cell Manipulator 600 (Biotechnology and Experimental Research, San Diego, CA) at 280 V and 960 μF. Stably transfected clones were selected by addition of genetin to a final concentration of 700 μg/ml. The clone that exhibited maximum shift in fluorescence upon stimulation with TNFα was used in experiments.

Measuring NFκB and MAPK activity

Endothelial cells were stimulated with different dose of dsDNA ranging from 0 to 4 μg/ml for 6 hours. Nuclear extract was prepared from cells using Panomics Nuclear Extraction Kit (Affymetrix, Inc., Santa Clara, CA) as per manufacturer’s protocol. Nuclear extracts were kept frozen in −80°C until further analysis. NFκB activity was determined by estimating the levels of NFκB p65 protein in the nuclear extract using ELISA kit (TransFactor NFκB p65 kit, Clontech, Mountain View, CA) according to manufacturer’s instructions. Samples were normalized by total protein concentration of the nuclear extract, determined by Bradford reagent.

Endothelial cells were stimulated with dsDNA (2 μg/ml) for 6 hours in 96 well plate. Phosphorylated protein levels of JNK, p38 MAPK, and ERK1/2 were determined using cell based ELISA kit (RayBio Cell-Based ERK1/2 ELISA Sampler Kit, Ray Biotech Inc., Norcross, GA) as per manufacturer’s instructions.

Animals

C57BL/6 and TNFR1−/− mice were purchased from Jackson Laboratory. All animal protocols were approved by Massachusetts General Hospital Subcommittee on Research Animal Care.

dsDNA-induced inflammation

dsDNA was complexed with LyoVec transfection reagent according to the manufacturer’s protocol (Invivogen). DNase I digested DNA was prepared by treating 100 μg of DNA with 5 U of DNase I (Ambion) at 37°C for 30 minutes. DNase was then heat inactivated, and the digested DNA was complexed with LyoVec. Mice were injected intraperitoneally with dsDNA (2 mg/kg) in .1 mL PBS, DNase digested DNA (2 mg/kg) in .1 mL PBS, or PBS alone. At 16 hours after challenge, the numbers of neutrophils (Ly-6G+) in the peritoneum were evaluated as previously described [41]. For each condition, 5 animals were used.

Statistical Analysis

Results are reported as mean ± standard deviation. Statistical analysis was performed using the Student’s t-test, with P<0.05 considered significant.
