(Received 19 March 2011; published 27 April 2011)

We predict the existence of coupled plasmon-phonon excitations in graphene by using the self-consistent linear response formalism. The unique electron-phonon interaction in graphene leads to unconventional mixing of plasmon and optical phonon polarizations. We find that longitudinal plasmons couple exclusively to transverse optical phonons, whereas graphene’s transverse plasmons couple only to longitudinal optical phonons. This coupling can serve as a magnifier for exploring the electron-phonon interaction in graphene, and it offers electronic control over phonon frequencies.

DOI: 10.1103/PhysRevB.83.161409 PACS number(s): 73.20.Mf, 73.22.Lp, 63.22.Rc, 78.67.Wj

The interaction of electrons and crystal lattice vibrations (phonons) has fundamental implications for properties of materials and leads to diverse many-body phenomena, such as superconductivity and charge-density waves. The electron-phonon interaction takes an unusual form in graphene, a two-dimensional (2D) material,6–12 and its implications are far from being explored. These include the breakdown of the Born-Oppenheimer approximation,3 the anomaly of the optical phonon,4 and the nonadiabatic Khon anomaly.5 However, the interaction of collective electron excitations (plasmons) and optical phonons has not yet been presented for graphene. Plasmons in graphene are of fundamental scientific interest,6–12 but they also hold potential for technological applications (e.g., in the context of plasmon lasers9 and metamaterials12). The long-wavelength in-plane optical phonon branch in graphene consists of two modes (LO and TO), which are effectively dispersionless and degenerate at energy $\bar{h} \nu_F$, where $\nu_F = 10^6$ m/s, $k = (k_x, k_y) = -i \nabla$ is the wave-vector operator, $\sigma = (\sigma_x, \sigma_y)$, and $\sigma_{\alpha\beta}$ are the Pauli spin matrices. We label the eigenstates of Hamiltonian $H_e$ by $|s, k\rangle$, and the appropriate eigenvalues by $E_{s, k} = \bar{h} \nu_F |k\rangle$, where $s = 1$ for the conduction band and $s = -1$ for the valence band. A technologically interesting property of graphene is that the concentration of electrons $n$, and hence the Fermi level $E_F = \bar{h} \nu_F \sqrt{\pi n}$, can be changed via gate voltage.1

The long-wavelength limit of optical phonon branch in graphene consists of two modes (LO and TO), which are effectively dispersionless and degenerate at energy $\bar{h} \nu_0 = 0.196$ eV.24 Let $u(R) = [u_A(R) - u_B(R)]/\sqrt{2}$ denote the relative displacements of the sublattice atoms $A$ and $B$ of a unit cell specified by a coordinate $R$ [see Fig. 1(c)]. Then, in the long-wavelength limit $R$ can be replaced with a continuous coordinate $r$ and we have

$$u(r) = \sum_{\mu q} \frac{1}{\sqrt{NM}} Q_{\mu q} e^{i\mu q r},$$

where $N$ is the number of unit cells, $M$ is the carbon atom mass, $q = q (\cos \phi_q, \sin \phi_q)$ is the phonon wave vector, $\mu = L, T$ stands for the polarization, and the polarization unit vectors are $e_L q = i (\cos \phi_q, \sin \phi_q)$ and $e_T q = i (- \sin \phi_q, \cos \phi_q)$. The displacement vector $u(r)$ is parallel (perpendicular) to the phonon propagation wave vector $q$ for LO (TO, respectively) phonons [see Fig. 1(c)]. The phonon Hamiltonian is given by

$$H_{ph} = \frac{1}{2} \sum_{\mu q} \left( P_{\mu q}^\dagger P_{\mu q} + \omega_q^2 Q_{\mu q}^\dagger Q_{\mu q} \right),$$

where $Q_{\mu q}$ and $P_{\mu q}$ denote phonon coordinate and momentum. The electron-phonon interaction takes a peculiar form in graphene

$$H_{e-ph} = - \sqrt{2} \frac{\bar{h} \nu_F}{\hbar^2} \sigma \times u(r),$$

where $\sigma = (\sigma_x, \sigma_y, \sigma_z)$ are the Pauli spin matrices, $\bar{h} \nu_F = 10^6$ m/s, $k = (k_x, k_y) = -i \nabla$ is the wave-vector operator, $\sigma = (\sigma_x, \sigma_y)$, and $\sigma_{\alpha\beta}$ are the Pauli spin matrices. We label the eigenstates of Hamiltonian $H_e$ by $|s, k\rangle$, and the appropriate eigenvalues by $E_{s, k} = \bar{h} \nu_F |k\rangle$, where $s = 1$ for the conduction band and $s = -1$ for the valence band. A technologically interesting property of graphene is that the concentration of electrons $n$, and hence the Fermi level $E_F = \bar{h} \nu_F \sqrt{\pi n}$, can be changed via gate voltage.1

The long-wavelength limit of optical phonon branch in graphene consists of two modes (LO and TO), which are effectively dispersionless and degenerate at energy $\bar{h} \nu_0 = 0.196$ eV.24 Let $u(R) = [u_A(R) - u_B(R)]/\sqrt{2}$ denote the relative displacements of the sublattice atoms $A$ and $B$ of a unit cell specified by a coordinate $R$ [see Fig. 1(c)]. Then, in the long-wavelength limit $R$ can be replaced with a continuous coordinate $r$ and we have

$$u(r) = \sum_{\mu q} \frac{1}{\sqrt{NM}} Q_{\mu q} e^{i\mu q r},$$

where $N$ is the number of unit cells, $M$ is the carbon atom mass, $q = q (\cos \phi_q, \sin \phi_q)$ is the phonon wave vector, $\mu = L, T$ stands for the polarization, and the polarization unit vectors are $e_L q = i (\cos \phi_q, \sin \phi_q)$ and $e_T q = i (- \sin \phi_q, \cos \phi_q)$. The displacement vector $u(r)$ is parallel (perpendicular) to the phonon propagation wave vector $q$ for LO (TO, respectively) phonons [see Fig. 1(c)]. The phonon Hamiltonian is given by

$$H_{ph} = \frac{1}{2} \sum_{\mu q} \left( P_{\mu q}^\dagger P_{\mu q} + \omega_q^2 Q_{\mu q}^\dagger Q_{\mu q} \right),$$

where $Q_{\mu q}$ and $P_{\mu q}$ denote phonon coordinate and momentum. The electron-phonon interaction takes a peculiar form in graphene

$$H_{e-ph} = - \sqrt{2} \frac{\bar{h} \nu_F}{\hbar^2} \sigma \times u(r),$$

where $\sigma = (\sigma_x, \sigma_y, \sigma_z)$ are the Pauli spin matrices, $\bar{h} \nu_F = 10^6$ m/s, $k = (k_x, k_y) = -i \nabla$ is the wave-vector operator, $\sigma = (\sigma_x, \sigma_y)$, and $\sigma_{\alpha\beta}$ are the Pauli spin matrices. We label the eigenstates of Hamiltonian $H_e$ by $|s, k\rangle$, and the appropriate eigenvalues by $E_{s, k} = \bar{h} \nu_F |k\rangle$, where $s = 1$ for the conduction band and $s = -1$ for the valence band. A technologically interesting property of graphene is that the concentration of electrons $n$, and hence the Fermi level $E_F = \bar{h} \nu_F \sqrt{\pi n}$, can be changed via gate voltage.1
the Brillouin zone. (c) A displacement of lattice atoms with two sublattices (HeBy comparing Eqs. (4) and (6) it follows that electron-phonon interaction can be regarded as a presence of an effective vector potential $A_{\text{eff}}$ perpendicular to $u(r)$ (the sign of $A_{\text{eff}}$ for the $K'$ point is opposite to that for the $K$ point).

where $\sigma \times u = \sigma_x u_y - \sigma_y u_x$, $b = 0.142$ nm is the nearest carbon atoms distance, and $\beta = 2$. We find it convenient to write Eq. (4) as

$$H_{e-\text{ph}} = L^2 F \sum_{\mu q} j_q \times e_{\mu q} Q_{\mu q}, \quad (5)$$

where $j_q = -e v_F L^2 \sigma e^{-i\omega t}$ is the single-particle current-density operator, $L^2$ is the area of the system, $-e$ is charge of the electron, and $F = \frac{\sqrt{2 \hbar \omega}}{c} \sqrt{N/M}$.

The electromagnetic field in the plane of graphene is completely described by the vector potential $A = \sum_{\mu q} e_{\mu q} A_{\mu q} e^{i\omega t}$ (scalar potential is gauged to zero, time dependence is implicitly assumed, and $\mu = L, T$ denote polarizations). The interaction with Dirac electrons is obtained by substitution $\hbar k \rightarrow \hbar k + eA$ in Eq. (1), which leads to

$$H_{e-\text{em}} = e v_F \sigma \cdot A = -L^2 \sum_{\mu q} j_q \cdot e_{\mu q} A_{\mu q}. \quad (6)$$

By comparing Eqs. (4) and (6) it follows that electron-phonon interaction can be regarded as a presence of an effective vector potential,

$$A_{\text{eff}} = F \sum_{q} (e_{Tq} Q_{Lq} - e_{Lq} Q_{Tq}) e^{i\omega t}. \quad (7)$$

that is, $H_{e-\text{ph}} = e v_F \sigma \cdot A_{\text{eff}}$. It is evident that $A_{\text{eff}} \cdot u(r) = 0$ that is the effective vector potential $A_{\text{eff}}$ is perpendicular to $u(r)$ as illustrated in Figs. 1(c) and 1(d) (see also Ref. 2), which is responsible for the mixing of polarizations in plasmon-phonon coupling. This result is strictly valid only in the long-wavelength limit.

As a first pass, let us ignore the phonons and focus on the Hamiltonian $H = H_e + H_{e-\text{em}}$. Without an external perturbation, the electrons in graphene fill the Fermi sea according to the Fermi distribution function $f_{\text{Eq}}$. A field $A_{\mu q}(\omega)$ oscillating at frequency $\omega$ will induce an average current density (up to a linear order in the vector potential)

$$\langle J_{\mu}(q, \omega) \rangle = -\chi_{\mu}(q, \omega) A_{\mu q}(\omega), \quad (8)$$

where the current-current response function (including two-spin and two-valley degeneracy) is given by

$$\chi_{\mu}(q, \omega) = 4 L^2 \sum_{\alpha=\pm} \frac{f_{\text{Eq}} - f_{\text{E0}}}{\hbar \omega + \hbar \alpha q - \hbar q_{\alpha} + i\eta} \times |S_{\alpha}(k, q) e^{-i\omega T} |^2 . \quad (9)$$

For the response function $\chi_{\mu}(q, \omega)$ we utilize the analytical expression from Ref. 27. The subtlety involved with the divergence in Eq. (9) is solved by subtracting from $\chi_L(q, \omega)$ [$\chi_T(q, \omega)$] the value $\chi_L(q, \omega = 0) [\chi_T(q \rightarrow 0, \omega = 0)]$ to take into account that there is no current response to the longitudinal [transverse] time [time and space] independent vector potential (see Refs. 27 and 28 for details). We would like to note that when working with the current-current response function, rather than with the density-density response function, the nature of the plasmon-phonon interaction (especially the mixing of polarizations as shown below) is far more transparent.

Next, it is straightforward to show from the Maxwell equations that an electric current oscillating in a 2D plane will induce a vector potential

$$\langle A_{Lq}(\omega) \rangle = \langle J_L(q, \omega) \rangle \frac{\sqrt{q^2 - \omega^2/c^2}}{-2\omega^2 e_0}, \quad (10)$$

and

$$\langle A_{Tq}(\omega) \rangle = \langle J_T(q, \omega) \rangle \frac{\mu_0}{2\sqrt{q^2 - \omega^2/c^2}}, \quad (11)$$

where $\chi_L(q, \omega) = 0$. From Eqs. (8) and (10) we get the dispersion relation for longitudinal plasmons:

$$1 - \frac{q^2 - \omega^2/c^2}{2\omega^2 e_0} \chi_L(q, \omega) = 0. \quad (12)$$

From Eqs. (8) and (11) we get the dispersion relation for TPs:

$$1 + \frac{\mu_0}{2\sqrt{q^2 - \omega^2/c^2}} \chi_T(q, \omega) = 0. \quad (13)$$

Longitudinal plasmons are also referred to as transverse magnetic modes (TM) since they are accompanied by a longitudinal electric field ($E$) and a transverse magnetic field ($B$) in the plane of graphene. Likewise, TPs or transverse electric modes are accompanied by a transverse electric and a longitudinal magnetic field. Dispersion relation of LP (TP) modes is shown by the blue dashed line in Fig. 2. (Figure 3, respectively.) Finally we note that we are primarily interested in nonradiative modes ($q > \omega/c$) in which case fields are localized near the graphene plane ($z = 0$) and decay exponentially: $E(z), B(z) \propto e^{-|z|/\sqrt{q^2 - \omega^2/c^2}}$.

In order to find the plasmon-phonon coupled excitations we consider the complete Hamiltonian $H = H_e + H_{e-\text{em}} + \chi_{\mu}(q, \omega) A_{\mu q}(\omega)$. The current-current response function (including two-spin and two-valley degeneracy) is given by

$$\chi_{\mu}(q, \omega) = 4 L^2 \sum_{\alpha=\pm} \frac{f_{\text{Eq}} - f_{\text{E0}}}{\hbar \omega + \hbar \alpha q - \hbar q_{\alpha} + i\eta} \times |S_{\alpha}(k, q) e^{-i\omega T} |^2 . \quad (9)$$

For the response function $\chi_{\mu}(q, \omega)$ we utilize the analytical expression from Ref. 27. The subtlety involved with the divergence in Eq. (9) is solved by subtracting from $\chi_L(q, \omega)$ [$\chi_T(q, \omega)$] the value $\chi_L(q, \omega = 0) [\chi_T(q \rightarrow 0, \omega = 0)]$ to take into account that there is no current response to the longitudinal [transverse] time [time and space] independent vector potential (see Refs. 27 and 28 for details). We would like to note that when working with the current-current response function, rather than with the density-density response function, the nature of the plasmon-phonon interaction (especially the mixing of polarizations as shown below) is far more transparent.

Next, it is straightforward to show from the Maxwell equations that an electric current oscillating in a 2D plane will induce a vector potential

$$\langle A_{Lq}(\omega) \rangle = \langle J_L(q, \omega) \rangle \frac{\sqrt{q^2 - \omega^2/c^2}}{-2\omega^2 e_0}, \quad (10)$$

and

$$\langle A_{Tq}(\omega) \rangle = \langle J_T(q, \omega) \rangle \frac{\mu_0}{2\sqrt{q^2 - \omega^2/c^2}}, \quad (11)$$

where $\chi_L(q, \omega) = 0$. From Eqs. (8) and (10) we get the dispersion relation for longitudinal plasmons:

$$1 - \frac{q^2 - \omega^2/c^2}{2\omega^2 e_0} \chi_L(q, \omega) = 0. \quad (12)$$

From Eqs. (8) and (11) we get the dispersion relation for TPs:

$$1 + \frac{\mu_0}{2\sqrt{q^2 - \omega^2/c^2}} \chi_T(q, \omega) = 0. \quad (13)$$

Longitudinal plasmons are also referred to as transverse magnetic modes since they are accompanied by a longitudinal electric field ($E$) and a transverse magnetic field ($B$) in the plane of graphene. Likewise, TPs or transverse electric modes are accompanied by a transverse electric and a longitudinal magnetic field. Dispersion relation of LP (TP) modes is shown by the blue dashed line in Fig. 2. (Figure 3, respectively.) Finally we note that we are primarily interested in nonradiative modes ($q > \omega/c$) in which case fields are localized near the graphene plane ($z = 0$) and decay exponentially: $E(z), B(z) \propto e^{-|z|/\sqrt{q^2 - \omega^2/c^2}}$.

In order to find the plasmon-phonon coupled excitations we consider the complete Hamiltonian $H = H_e + H_{e-\text{em}} + \chi_{\mu}(q, \omega) A_{\mu q}(\omega)$.
and from Eqs. (11), (15), and (17) the dispersion relation for the TP-LO coupled mode,

\[ \omega_0^2 - \omega^2 = \frac{L^2 \hbar^2 \omega}{1 + \sqrt{\frac{\omega}{\omega_0}} \chi_T(q, \omega)} \]  \hspace{1cm} (19)

The plasmon dispersions relations (12) and (13) appear as poles in Eqs. (18) and (19) for the coupled modes, which means that the coupling is greatest at the resonance point where plasmon momentum and energy match that of the appropriate phonon mode. We denote this point (where the uncoupled plasmon and phonon dispersion cross) by \( (q_0, \omega_0) \). One can quantify the strength of the coupling effect by calculating the frequency difference between the hybrid modes at the wave vector \( q_c \) in units of the uncoupled frequency value: \( \Delta \omega / \omega_0 \).

Finally, by doping one can change plasmon dispersion which in turn changes \( q_c \) and the strength of the plasmon-phonon coupling.

The dispersion lines for the hybrid LP-TO modes are shown in Fig. 2 for two values of doping: (a) \( n = 5 \times 10^{12} \) cm\(^{-2} \) and (b) \( n = 5 \times 10^{13} \) cm\(^{-2} \). The plasmonlike dispersion is very close to the light line \( q = \omega / c \); therefore, the ordinate shows \( \Delta q = q - \omega / c \).

FIG. 2. (Color online) Dispersion lines of hybrid LP-TO plasmon-phonon modes (solid lines) and of the uncoupled modes (dashed lines) for two values of doping: (a) \( n = 5 \times 10^{12} \) cm\(^{-2} \) and (b) \( n = 5 \times 10^{13} \) cm\(^{-2} \). Gray areas denote the region of single-particle damping.
strength of the coupling for TP-LO modes is in general much weaker than in LP-TO modes.

Before closing, we note another interesting result which is captured by our calculations. Equations (18) and (19) for shifts in the energies of TO and LO modes at \( q = 0 \) reduce to

\[
\omega^2 - \omega_0^2 = \frac{L^2 F^2 \chi_{L,T}(0,\omega)}{1 + \frac{1}{2\omega_0^2} \chi_{L,T}(0,\omega)},
\]

which is identical to the result of Ref. 4, where the coupling of optical phonons to single-particle excitations was studied, apart from the imaginary term in the denominator, which is zero in Ref. 4. This small but qualitative difference is a consequence of phonon coupling to the radiative electromagnetic modes, which increases the phonon linewidth. For example, for the doping values of \( n = 5 \times 10^{12} \text{ cm}^{-2}, 5 \times 10^{13} \text{ cm}^{-2}, \) and \( 5 \times 10^{14} \text{ cm}^{-2} \), Eq. (20) yields 0.005%, 0.07%, and 0.7%, respectively, for the linewidths, while there is no linewidth from single-particle damping at these doping values. This effect is qualitatively unchanged for graphene sitting on a substrate and could be measured by Raman spectroscopy. Finally, we note an interesting solution of Eq. (19) (valid for suspended graphene): When the hybrid TP-LO mode dispersion crosses the light line it has the same energy for the uncoupled phonon mode, that is, \( \omega = \omega_0 \). In other words, the LO phonon at a wave vector \( q = \omega_0/c \) decouples from all single and collective electron excitations, while no such effect exists for the TO phonons.

In conclusion, we have predicted hybridization of plasmons and intrinsic optical phonons in graphene using self-consistent linear response theory. We found that graphene’s unique electron-phonon interaction leads to unconventional mixing of plasmon and optical phonon polarizations: Longitudinal plasmons couple exclusively to TO phonons, whereas graphene’s TPs couple to LO phonons; this contrasts plasmon-phonon coupling in all previously studied systems. The strength of the hybridization increases with doping in LP-TO coupled modes, while the trend is opposite for TP-LO modes. The LP-TO coupling is much stronger than TP-LO coupling, and it could be measured by current experiments to explore the electron-phonon interaction in graphene (the frequency shifts at resonance are much larger than those recently measured by Raman spectroscopy). This coupling is an even more striking example of a breakdown of Born-Oppenheimer approximation in graphene than the recently measured stiffening of the Raman G peak. Moreover, plasmon-phonon interaction can serve to electronically control the frequencies of lattice vibrations in graphene, which could have interesting technological implications.
