Abstract

Berger and Colmez introduced a theory of families of overconvergent étale \((\varphi, \Gamma)\)-modules associated to families of \(p\)-adic Galois representations over \(p\)-adic Banach algebras. However, in contrast with the classical theory of \((\varphi, \Gamma)\)-modules, the functor they obtain is not an equivalence of categories. In this paper, we prove that when the base is an affinoid space, every family of (overconvergent) étale \((\varphi, \Gamma)\)-modules can locally be converted into a family of \(p\)-adic representations in a unique manner, providing the “local” equivalence. There is a global mod \(p\) obstruction related to the moduli of residual representations.

Introduction

In [3], Berger and Colmez introduced a theory of families of overconvergent étale \((\varphi, \Gamma)\)-modules associated to families of \(p\)-adic Galois representations over \(p\)-adic Banach algebras. The \(p\)-adic families of local Galois representations emerging from number theory are usually over rigid analytic spaces. So we are mainly interested in the case where the bases are reduced affinoid spaces. However, even in this case the functor of Berger-Colmez is far from an equivalence of categories, in contrast with the classical theory of \((\varphi, \Gamma)\)-modules. This was first noticed by Chenevier [3, Remarque 4.2.10]: if the base is the \(p\)-adic unit circle \(M(Q_p(X,Y)/(XY - 1))\), then it is easy to see that the free rank 1 overconvergent étale \((\varphi, \Gamma)\)-module \(D\) with a basis \(e\) such that \(\varphi(e) = Ye\) and \(\gamma(e) = e\) for \(\gamma \in \Gamma\) does not come from a family of \(p\)-adic representations over the same base.

On the other hand, in his proof of the density of crystalline representations, Colmez proved [8, Proposition 5.2] that for certain families of rank 2 triangular étale \((\varphi, \Gamma)\)-modules, one can locally convert such a family into a family of \(p\)-adic representations using his theory of Espaces Vectoriels de dimension finie (it is clear that we can also convert Chenevier’s example locally). Moreover, Colmez remarked [8, Remarque 5.3(2)] that: On aurait pu aussi utiliser une version «en famille» des théorèmes à la Dieudonné-Manin de Kedlaya. Il y a d’ailleurs une concordance assez frappante entre ce que permettent de démontrer ces théorèmes de Kedlaya et la théorie des Espaces Vectoriels de dimension finie.
Unfortunately, as noticed in [16], there is no family version of Kedlaya’s slope filtrations theorem in general, because the slope polygons of families of Frobenius modules are not necessarily locally constant. Nonetheless, one may still ask to what extent one can convert a globally étale family of \((\phi, \Gamma)\)-modules back into a Galois representation. As Chenevier’s example shows, this cannot be done in general over an affinoid base. The best one can hope for in general is the following theorem, which extends a result of Dee [9]. (In the statement, the distinction between a \((\phi, \Gamma)\)-module and a family of \((\phi, \Gamma)\)-modules is that the former is defined as a module over a ring, whereas the latter is defined as a coherent sheaf over a rigid analytic space.)

**Theorem 0.1.** Let \(S\) be a Banach algebra over \(\mathbb{Q}_p\) of the form \(R \otimes_{\mathbb{Z}_p} \mathbb{Q}_p\), where \(R\) is a complete noetherian local domain of characteristic 0 whose residue field is finite over \(\mathbb{F}_p\). Then for any finite extension \(K\) of \(\mathbb{Q}_p\), the categories of \(S\)-linear representations of \(G_K\), of étale \((\phi, \Gamma)\)-modules over \(B^\dagger_{\text{rig}, K} \widehat{\otimes} \mathbb{Q}_p S\), and of families of étale \((\phi, \Gamma)\)-modules over \(B^\dagger_{\text{rig}, K} \widehat{\otimes} \mathbb{Q}_p S\) are all equivalent.

For instance, if \(S\) is an affinoid algebra and we are given an étale \((\phi, \Gamma)\)-module over \(B^\dagger_{\text{rig}, K} \widehat{\otimes} \mathbb{Q}_p S\), we recover a linear representation over each residue disc of \(S\) (and every affinoid subdomain of such a disc), but these representations may not glue. This is what happens in Chenevier’s example, because the mod \(p\) representations cannot be uniformly trivialized. In fact, the obstruction to converting a \((\phi, \Gamma)\)-module back into a representation exists purely at the residual level; it suggests a concrete realization of the somewhat murky notion of “moduli of residual (local) representations”.

By combining Theorem with the results of [16], we obtain a result that applies when only one fibre of the \((\phi, \Gamma)\)-module is known to be étale. (Beware that the natural analogue of this statement in which the rigid analytic point \(x\) is replaced by a Berkovich point is trivially false.)

**Theorem 0.2.** Let \(S\) be an affinoid algebra over \(\mathbb{Q}_p\), and let \(M_S\) be a family of \((\phi, \Gamma)\)-modules over \(B^\dagger_{\text{rig}, K} \widehat{\otimes} \mathbb{Q}_p S\). If \(M_x\) is étale for some \(x \in M(S)\), then there exists an affinoid neighborhood \(M(B)\) of \(x\) and a \(B\)-linear representation \(V_B\) of \(G_K\) whose associated \((\phi, \Gamma)\)-module is isomorphic to \(M_S \widehat{\otimes}_S B\). Moreover, \(V_B\) is unique for this property.

In [2], to prove the Fontaine-Colmez theorem, Berger constructed a morphism from the category of filtered \((\phi, N)\)-modules to the category of \((\phi, \Gamma)\)-modules. It should be possible to generalize Berger’s construction to families of filtered \((\phi, N)\)-modules; upon doing so, one would get a family version of the Fontaine-Colmez theorem by the preceding theorem. That is, one would know that a weakly admissible family of filtered \((\phi, N)\)-modules over an affinoid base (with trivial \(\phi\)-action on the base) becomes admissible in a neighborhood of each rigid analytic point.

**Acknowledgments**

The first author thanks Siegfried Bosch for helpful comments. The second author thanks Pierre Colmez for the helpful conversation during spring 2008 which inspired this project, Laurent Berger for answering many questions patiently, and Marie-France Vignéras for arranging his visit to Institut de Mathématiques de Jussieu during spring 2008. While writing this paper, the first author was supported by NSF CAREER grant DMS-0545904, the MIT NEC Research Support Fund, and the MIT Cecil and Ida Green Career Development Professorship, while the second author was a postdoctoral fellow of Foundation Sciences Mathématiques de Paris.
1 Rings of $p$-adic Hodge theory

We begin by introducing some of the rings used in $p$-adic Hodge theory. This is solely to fix notation; we do not attempt to expose the constructions in any detail. For that, see for instance [1]. In what follows, whenever a ring is defined whose notation includes a boldface $\mathbf{A}$, the same notation with $\mathbf{A}$ replaced by $\mathbf{B}$ will indicate the result of inverting $p$.

Let $\mathbb{C}_p$ be a completed algebraic closure of $\mathbb{Q}_p$, with valuation subring $\mathcal{O}_{\mathbb{C}_p}$ and $p$-adic valuation $v_p$ normalized with $v_p(p) = 1$. Let $\overline{\nu}_p : \mathcal{O}_{\mathbb{C}_p} / (p) \to [0, 1] \cup \{+\infty\}$ be the semivaluation obtained by truncation. Define $\mathbf{E}^+$ to be the ring of sequences $(x_n)_{n=0}^{\infty}$ in $\mathcal{O}_{\mathbb{C}_p} / (p)$ such that $x_{n+1} = x_n$ for all $n$. Define a function $v_E : \mathbf{E}^+ \to [0, +\infty]$ by sending the zero sequence to $+\infty$, and sending each nonzero sequence $(x_n)$ to the common value of $p^n\overline{\nu}_p(x_n)$ for all $n$ with $x_n \neq 0$. This gives a valuation under which $\mathbf{E}^+$ is complete. Moreover, if we put $E = \text{Frac}(\mathbf{E}^+)$, and let $e = (e_n)$ be an element of $\mathbf{E}^+$ with $e_0 = 1$ and $e_1 \neq 1$, then $\mathbf{E}$ is a completed algebraic closure of $\mathbb{F}_p((\epsilon - 1))$.

Let $\tilde{\mathbf{A}}$ be the $p$-typical Witt ring $W(\mathbf{E})$, which is the unique complete discrete valuation ring with maximal ideal $(p)$ and residue field $\mathbf{E}$. For each positive integer $n$, $W(\mathbf{E})/p^nW(\mathbf{E})$ inherits a topology from the valuation topology on $\mathbf{E}$, under which it is complete. We call the inverse limit of these the weak topology on $\tilde{\mathbf{A}}$. We similarly obtain a weak topology on $\tilde{\mathbf{B}}$.

For any $n \geq 0$, we let $\mu_{p^n}$ denote the set of $p^n$-th roots of unity in $\mathbb{Q}_p$, and let $\mu_{p^n} = \cup_{n \geq 0} \mu_{p^n}$. For $K$ a finite extension of $\mathbb{Q}_p$, let $K_{\infty} = K(\mu_{p^n})$, $H_K = \text{Gal}(K/K_{\infty})$, $\Gamma = \text{Gal}(K_{\infty}/K)$ and $K_0 = \mathbb{Q}_p^{ur} \cap K_{\infty}$.

Put $\pi = [e] - 1$, where brackets denote the Teichmüller lift. Using the completeness of $\tilde{\mathbf{A}}$ for the weak topology, we may embed $\mathbb{Z}_p((\pi))$ into $\tilde{\mathbf{A}}$. Let $\mathbf{A}$ be the $p$-adic completion of the integral closure of $\mathbb{Z}_p((\pi))$ in $\tilde{\mathbf{A}}$, and put $\mathbf{A}_K = \mathbf{A}^{H_K}$. These rings carry actions of $G_K$ which are continuous for the weak topology on the rings and the profinite topology on $G_K$. They also carry endomorphisms $\varphi$ (which are weakly and $p$-adically continuous) induced by the Witt vector Frobenius on $\mathbf{A}$.

For $s > 0$, the subset
\[
\tilde{\mathbf{A}}^{+s} = \{ x \in \tilde{\mathbf{A}} : x = \sum_{k \in \mathbb{Z}} p^k [x_k], v_E(x_k) + \frac{ps}{p - 1} \geq 0, \lim_{k \to +\infty} v_E(x_k) = +\infty \}
\]
is a subring of $\tilde{\mathbf{A}}$ which is complete for the valuation
\[
w_s(x) = \inf_k \left\{ v_E(x_k) + \frac{ps}{p - 1} \right\}.
\]
Put $\tilde{\mathbf{B}} = \cup_{s > 0} \tilde{\mathbf{B}}^{+s}$, $\mathbf{B}_K = \mathbf{B}_K^{+s}$, $\mathbf{B}_K = \cup_{s \geq 0} \mathbf{B}_K^{+s}$, $\mathbf{A}_K = \mathbf{A}_K^{+s}$, $\mathbf{A}_K = \mathbf{A} \cap \tilde{\mathbf{B}}$. (Beware that the latter ring is strictly larger than $\cup_{s > 0} \mathbf{A}_K^{+s}$.) These rings carry an action of $\varphi$; for $n$ a positive integer, write
\[
\mathbf{A}_K^{+n} = \varphi^{-n}(\mathbf{A}_K^{+n}).
\]
Let $\tilde{\mathbf{B}}_{\text{rig}}^{+s}$ be the Fréchet completion of $\tilde{\mathbf{B}}^{+s'}$ under the valuations $w_{s'}$ for all $s' \geq s$, and put $\tilde{\mathbf{B}}_{\text{rig}}^{+s} = \cup_{s > 0} \tilde{\mathbf{B}}_{\text{rig}}^{+s}$. Similarly, let $\mathbf{B}_{\text{rig}}^{+s}$ be the Fréchet completion of $\mathbf{B}_K^{+s}$ under the valuations $w_{s'}$ for all $s' \geq s$, and put $\mathbf{B}_{\text{rig}}^{+s} = \cup_{s > 0} \mathbf{B}_{\text{rig}}^{+s}$. It turns out that $(\mathbf{B}_{\text{rig}}^{+s})^{H_K} = \mathbf{B}_{\text{rig}}^{+s}$. 

3
Some of these rings admit more explicit descriptions, as follows. It turns out that \( B_K \) is isomorphic to the \( p \)-adic local field

\[
\mathcal{E}_{K_0'} = \{ f = \sum_{i=-\infty}^{+\infty} a_i T^i \mid a_i \in K_0', \inf \{ v_p(a_i) \} > -\infty, \lim_{i \to -\infty} v_p(a_i) = +\infty \}
\]

with valuation \( w(f) = \min_{i \in \mathbb{Z}} v_p(a_i) \) and imperfect residue field \( k'((T)) \), where \( k' \) is the residue field of \( K_0' \). There is no distinguished such isomorphism in general (except for \( K = \mathbb{Q}_p \), where one may take \( T = \pi \)), but suppose we fix a choice. Then \( B \) corresponds to the completion of the maximal unramified extension of \( B_K \). For \( s > 0 \) (depending on \( K \) and the choice of the isomorphism \( B_K \cong \mathcal{E}_{K_0'} \), \( B_K^{is} \) corresponds to the subring \( \mathcal{E}_{K_0'}^{is} \) of \( \mathcal{E}_{K_0'} \) defined as

\[
\mathcal{E}_{K_0'}^{is} = \{ f = \sum_{i=-\infty}^{+\infty} a_i T^i \mid a_i \in K_0', \inf \{ v_p(a_i) \} > -\infty, \lim_{i \to -\infty} i + \frac{ps}{p-1} v_p(a_i) = +\infty \},
\]

i.e., the bounded Laurent series in \( T \) convergent on the annulus \( 0 < v_p(T) \leq 1/s \). Meanwhile, \( B_{rig,K}^{is} \) corresponds to the ring

\[
\mathcal{R}_{K_0'}^{is} = \{ f = \sum_{i=-\infty}^{+\infty} a_i T^i \mid a_i \in K_0', \lim_{i \to +\infty} i + r v_p(a_i) = +\infty \forall r > 0, \lim_{i \to -\infty} i + \frac{ps}{p-1} v_p(a_i) = +\infty \},
\]

i.e., the unbounded Laurent series in \( T \) convergent on the annulus \( 0 < v_p(T) \leq 1/s \). The union \( \mathcal{R}_{K_0'} = \bigcup_{s>0} \mathcal{R}_{K_0'}^{is} \) is commonly called the Robba ring over \( K_0' \).

## 2 \( p \)-adic representations and \( (\varphi, \Gamma) \)-modules

We next introduce \( p \)-adic representations and the objects of semilinear algebra used to describe them. Fix a finite extension \( K \) of \( \mathbb{Q}_p \). For \( R \) a topological ring, we will mean by an \( R \)-linear representation a finite \( R \)-module equipped with a continuous linear action of \( G_K \). (We will apply additional adjectives like “free”, which are to be passed through to the underlying \( R \)-module.) Fontaine [10] constructed a functor giving an equivalence of categories between \( \mathbb{Q}_p \)-linear representations and certain linear (or rather semilinear) algebraic data, as follows. (We may extend to \( L \)-linear representations for finite extensions \( L \) of \( \mathbb{Q}_p \), by restricting the coefficient field to \( \mathbb{Q}_p \) and then keeping track of the \( L \)-action separately.)

An étale \( \varphi \)-module over \( A_K \) is a finite module \( N \) over \( A_K \), equipped with a semilinear action of \( \varphi \), such that the induced \( A_K \)-linear map \( \varphi^* N \to N \) induced by the \( \varphi \)-action is an isomorphism. An étale \( \varphi \)-module over \( B_K \) is a finite module \( M \) over \( B_K \), equipped with a semilinear action of \( \varphi \), which contains an \( A_K \)-lattice \( N \) (i.e., a finite \( A_K \)-submodule such that the induced map \( N \otimes A_K B_K \to M \) is an isomorphism) which forms an étale \( \varphi \)-module over \( A_K \). An étale \( (\varphi, \Gamma) \)-module over \( A_K \) or \( B_K \) is an étale \( \varphi \)-module equipped with a semilinear action of \( \Gamma \) which commutes with the \( \varphi \)-action and is continuous for the profinite topology on \( \Gamma \) and the weak topology on \( A_K \). Note that an étale \( (\varphi, \Gamma) \)-module over \( B_K \) may contain an \( A_K \)-lattice which forms an étale \( \varphi \)-module over \( A_K \) but is not stable under \( \Gamma \); on the other hand, the images of such a lattice under \( \Gamma \) span another lattice which forms an étale \( \varphi \)-module over \( A_K \).
For $T$ a $\mathbb{Z}_p$-linear representation, define $D(T) = (A \otimes \mathbb{Z}_p T)^{H_K}$; this gives an $A_K$-module equipped with commuting semilinear actions of $\varphi$ and $\Gamma$. Similarly, for $V$ a $\mathbb{Q}_p$-linear representation, define $D(V) = (B \otimes \mathbb{Q}_p V)^{H_K}$.

**Theorem 2.1 (Fontaine).** The functor $T \mapsto D(T)$ (resp. $V \mapsto D(V)$) is an equivalence from the category of $\mathbb{Z}_p$-linear representations (resp. $\mathbb{Q}_p$-linear representations) of $G_K$ to the category of étale $(\varphi, \Gamma)$-modules over $A_K$ (resp. $B_K$); a quasi-inverse functor is given by $D \mapsto (A \otimes A_K D)^{\varphi=1}$ (resp. $D \mapsto (B \otimes B_K D)^{\varphi=1}$).

Dee [9] extended Fontaine’s results to families of $\mathbb{Z}_p$-representations, as follows. Let $R$ be a complete noetherian local ring whose residue field $k_R$ is finite over $\mathbb{F}_p$, equipped with the topology defined by its maximal ideal $m_R$; we may then view $R$ as a topological $\mathbb{Z}_p$-algebra. We form the completed tensor product $R \widehat{\otimes}_{\mathbb{Z}_p} A$ by completing the ordinary tensor product for the ideal $pA + m_R$, and similarly with $A$ replaced by $A_K$.

We define $(\varphi, \Gamma)$-modules and étale $(\varphi, \Gamma)$-modules over $R \widehat{\otimes}_{\mathbb{Z}_p} A_K$ by analogy with the definitions over $A_K$. For $T_R$ an $R$-representation, define $D(T_R) = ((R \widehat{\otimes}_{\mathbb{Z}_p} A) \otimes_R T_R)^{H_K}$. We then have the following result.

**Theorem 2.2 (Dee).** The functor $T_R \mapsto D(T_R)$ is an equivalence from the category of $R$-representations to the category of étale $(\varphi, \Gamma)$-modules over $R \widehat{\otimes}_{\mathbb{Z}_p} A_K$; a quasi-inverse functor is given by $D \mapsto ((R \widehat{\otimes}_{\mathbb{Z}_p} A) \otimes_R D)^{\varphi=1}$.

We next introduce a refinement of Fontaine’s result due to Cherbonnier and Colmez [7]. We define $(\varphi, \Gamma)$-modules and étale $(\varphi, \Gamma)$-modules over the rings $A_K^\dagger$ and $B_K^\dagger$ by analogy with the definitions over $A_K$ and $B_K$. For $V$ a $\mathbb{Q}_p$-linear representation, define $D_K^\dagger(V) = (B^\dagger \otimes \mathbb{Q}_p V)^{H_K}$ (where $B^\dagger = B \cap \hat{B}_q$) and $D_K^\dagger(V) = \bigcup_{r>0} D_K^\dagger_r(V) = (B^\dagger \otimes \mathbb{Q}_p V)^{H_K}$.

**Theorem 2.3 (Cherbonnier-Colmez).** For each $\mathbb{Q}_p$-linear representation $V$, there exists $r(V) > 0$ such that

$$D_K(V) = B_K \otimes_{B_K^\dagger} D_K^\dagger_r(V) \quad \text{for all } r \geq r(V).$$

Equivalently, $D_K^\dagger(V)$ is an étale $(\varphi, \Gamma)$-module over $B_K^\dagger$ of dimension $\dim_{\mathbb{Q}_p} V$. Therefore $V \mapsto D_K^\dagger(V)$ is an equivalence from the category of $p$-adic representations of $G_K$ to the category of étale $(\varphi, \Gamma)$-modules over $B_K^\dagger$. Furthermore, $D_K^\dagger(V)$ is the unique maximal étale $(\varphi, \Gamma)$-submodule of $D_K(V)$ over $B_K^\dagger$.

In [8], Berger and Colmez extended these results to families of $p$-adic representations. However, unlike Dee’s families, the families considered by Berger and Colmez are over Banach algebras over $\mathbb{Q}_p$. (Berger and Colmez are forced to make a freeness hypothesis on the representation space; we will relax this hypothesis later in the case of an affinoid algebra. See Definition [3,12])

For $S$ a commutative Banach algebra over $\mathbb{Q}_p$, let $O_S$ be the ring of elements of $S$ of norm at most 1, and let $I_S$ be the ideal of elements of $O_S$ of norm strictly less than 1. Note that it makes sense to form a completed tensor product with $S$ or $O_S$ when the other tensorand carries a norm under it is complete, e.g., for the rings $A^{l,s}, A^{l,s}_{L,n}, B^{l,s}, B^{l,s}_L$ using the norm corresponding to the valuation $w_s$. 

5
Proposition 2.4 ([3] Proposition 4.2.8]). Let $S$ be a commutative Banach algebra over $\mathbb{Q}_p$. Let $T_S$ be a free $\mathcal{O}_S$-linear representation of rank $d$. Let $L$ be a finite Galois extension of $K$ such that $G_L$ acts trivially on $T_S/12pT_S$. Then there exists $n(L,T_S) \geq 0$ such that for $n \geq n(L,T_S)$, $(\mathcal{O}_S \hat{\otimes}_p \tilde{A}^{(p-1)/p}) \otimes_{\mathcal{O}_S} T_S$ has a unique sub-$((\mathcal{O}_S \hat{\otimes}_p \tilde{A}^{(p-1)/p}) \otimes_{\mathcal{O}_S} T_S)$-module $D_{L,n}^{p-1/p}(T_S)$ which is free of rank $d$, is fixed by $H_L$, has a basis which is almost invariant under $\Gamma_L$ (i.e., for each $\gamma \in \Gamma_L$, the matrix of action of $\gamma$ on the basis has positive valuation), and satisfies

\[
(\mathcal{O}_S \hat{\otimes}_p \tilde{A}^{(p-1)/p}) \otimes_{\mathcal{O}_S} \mathcal{O}_S T_S = (\mathcal{O}_S \hat{\otimes}_p \tilde{A}^{(p-1)/p}) \otimes_{\mathcal{O}_S} T_S.
\]

Theorem 2.5 ([3] Théorème 4.2.9]). Let $S$ be a commutative Banach algebra over $\mathbb{Q}_p$. Let $V_S$ be an $S$-linear representation admitting a free Galois-stable $\mathcal{O}_S$-lattice $T_S$. There exists an $s(V_S) \geq 0$ such that for any $s \geq s(V_S)$, we may define

\[
D_K^{1,s}(V_S) = ((\mathcal{O}_S \hat{\otimes}_p B_L^{1,s}) \otimes_{\mathcal{O}_S} T_S) \mathcal{O}_S (\mathcal{O}_S \hat{\otimes}_p \tilde{B}^{1,s} (D_{L,n}^{p-1/p}(T_S)))^{H_K}
\]

for some $L,n$, so that the construction does not depend on the choices of $T_S$, $L,n$, and the following statements hold.

1. The $(\mathcal{O}_S \hat{\otimes}_p B_L^{1,s})$-module $D_K^{1,s}(V_S)$ is locally free of rank $d$.

2. The natural map $D_K^{1,s}(V_S) \otimes_{\mathcal{O}_S} B_L^{1,s} (S \hat{\otimes}_p \tilde{B}^{1,s}) \to V_S \otimes_{\mathcal{O}_S} (S \hat{\otimes}_p \tilde{B}^{1,s})$ is an isomorphism.

3. For any maximal ideal $m_x$ of $S$, for $V_x = V_S \otimes_{\mathcal{O}_S} (S/m_x)$, the natural map $D_K^{1,s}(V_S) \otimes_{\mathcal{O}_S} (S/m_x) \to D_K^{1,s}(V_x)$ is an isomorphism.

We put $S \hat{\otimes}_p B_K^1 = \cup_{s>0}(S \hat{\otimes}_p B_K^1)$ and $S \hat{\otimes}_p \tilde{B}^1 = \cup_{s>0}(S \hat{\otimes}_p \tilde{B}^{1,s})$. (Beware that $S \hat{\otimes}_p B_K^1$ does not necessarily embed into $S \hat{\otimes}_p \tilde{B}_K^1$, due to the incompatibility between the topologies used for the completed tensor products.) We then put

\[
D_K^1(V_S) = D_K^{1,s}(V_S) \otimes_{\mathcal{O}_S} (S \hat{\otimes}_p \tilde{B}^{1,s}) (S \hat{\otimes}_p B_K^1).
\]

We may recover $V_S$ from $D_K^1(V_S)$ as follows.

Lemma 2.6. We have $(S \hat{\otimes}_p \tilde{B}^1)^{\varphi=1} = S$.

Proof. We reduce at once to the case where $S$ is countably topologically generated over $\mathbb{Q}_p$. In this case, by [3] Proposition 2.7.2/3], we can find a Schauder basis of $S$ over $\mathbb{Q}_p$; in other words, there exists an index set $I$ such that $S$ is isomorphic as a topological $\mathbb{Q}_p$-vector space to the Banach space

\[
l^n(I, \mathbb{Q}_p) = \{(a_i)_{i \in I} | a_i \in \mathbb{Q}_p, a_i \to 0\}.
\]

(The supremum norm need only be equivalent to the Banach norm on $S$; the two need not be equal.) We can then write $S \hat{\otimes}_p \tilde{B}^1$, as a topological $\mathbb{Q}_p$-vector space, as

\[
l^n(I, \tilde{B}^1) = \{(a_i)_{i \in I} | a_i \in \tilde{B}^1, a_i \to 0\}.
\]

In this presentation, the $\varphi$-action carries $(a_i)_{i \in I}$ to $(\varphi(a_i))_{i \in I}$. It is then clear that $(S \hat{\otimes}_p \tilde{B}^1)^{\varphi=1} = (l^n(I, \tilde{B}^1))^{\varphi=1} = l^n(I, \mathbb{Q}_p) = S$. \qed
Proposition 2.7. We have

\[(D^\dagger_K(V_S) \otimes_{S \hat{\otimes}_{Q_p} B^\dagger_K} (S \hat{\otimes}_{Q_p} \hat{B}^\dagger))^\varphi = V_S.\]

Proof. From Theorem 2.5(2) we get \(D^\dagger_K(V_S) \otimes_{S \hat{\otimes}_{Q_p} B^\dagger_K} (S \hat{\otimes}_{Q_p} \hat{B}^\dagger) = V_S \otimes_S (S \hat{\otimes}_{Q_p} \hat{B}^\dagger).\) It follows that

\[(D^\dagger_K(V_S) \otimes_{S \hat{\otimes}_{Q_p} B^\dagger_K} (S \hat{\otimes}_{Q_p} \hat{B}^\dagger))^\varphi = V_S \otimes_S (S \hat{\otimes}_{Q_p} \hat{B}^\dagger)^\varphi = V_S\]

by Lemma 2.6.

This suggests that the object \(D^\dagger_K(V_S)\) merits the following definition.

Definition 2.8. Define a \((\varphi, \Gamma)\)-module over \(S \hat{\otimes}_{Q_p} B^\dagger_K\) to be a finite locally free module over \(S \hat{\otimes}_{Q_p} B^\dagger_K\), equipped with commuting continuous \((\varphi, \Gamma)\)-actions such that \(\varphi^* D_S \to D_S\) is an isomorphism. We say a \((\varphi, \Gamma)\)-module \(M_S\) over \(S \hat{\otimes}_{Q_p} B^\dagger_K\) is étale if it admits a finite \((\varphi, \Gamma)\)-stable \((O_S \hat{\otimes}_{z_p} A^\dagger_K)\)-submodule \(N_S\) such that \(\varphi^* N_S \to N_S\) is an isomorphism and the induced map

\[N_S \otimes_{O_S \hat{\otimes}_{z_p} A^\dagger_K} S \hat{\otimes}_{Q_p} B^\dagger_K \to M_S\]

is an isomorphism. In this language, Theorem 2.5 implies that \(D^\dagger_K(V_S)\) is an étale \((\varphi, \Gamma)\)-module over \(S \hat{\otimes}_{Q_p} B^\dagger_K\).

3 Gluing on affinoid spaces

Throughout this section, let \(S\) denote an affinoid algebra over \(Q_p\). We explain in this section how to perform gluing for finite modules over \(S \hat{\otimes}_{Q_p} B^\dagger_K\). We start with some basic notions from [5].

Definition 3.1. Let \(M(S)\) be the set of maximal ideals of \(S\), i.e., the affinoid space associated to \(S\). For \(X\) a subset of \(M(S)\), an affinoid subdomain of \(X\) is a subset \(U\) of \(X\) for which there exists a morphism \(S \to S'\) of affinoid algebras such that the induced map \(M(S') \to M(S)\) is universal for maps from an affinoid space to \(M(S)\) landing in \(U\). The algebra \(S'\) is then unique up to unique isomorphism, and the resulting map \(M(S) \to U\) is a bijection.

The set \(M(S)\) carries two canonical \(G\)-topologies, defined as follows. In the weak \(G\)-topology, the admissible open sets are the affinoid subdomains, and the admissible coverings are the finite coverings. In the strong \(G\)-topology, the admissible open sets are the subsets \(U\) of \(M(S)\) admitting a covering by affinoid subdomains such that the induced covering of any affinoid subdomain of \(U\) can be refined to a finite cover by affinoid subdomains, and the admissible coverings are the ones whose restriction to any affinoid subdomain can be refined to a finite cover by affinoid subdomains. The categories of sheaves on these two topologies are equivalent, because the strong \(G\)-topology is slightly finer than the weak one [5, §9.1].

We need a generalization of the Tate and Kiehl theorems on coherent sheaves on affinoid spaces.

Definition 3.2. For \(A\) a commutative Banach algebra over \(Q_p\), define the presheaf \(\mathcal{A}\) on the weak \(G\)-topology of \(M(S)\) by declaring that

\[\mathcal{A}(M(S')) = S' \hat{\otimes}_{Q_p} A.\]
Lemma 3.3. For $A$ a commutative Banach algebra over $\mathbb{Q}_p$, the presheaf $A$ is a sheaf for the weak $G$-topology of $M(S)$, and hence extends uniquely to the strong $G$-topology.

Proof. Since every finite covering of an affinoid space by affinoid subdomains can be refined to a Laurent covering, it is enough to check the sheaf condition for Laurent coverings [5 Proposition 8.2.2/5]. This reduces to checking for coverings of the form

$$M(S) = M(S(f)) \cup M(S(f^{-1}))$$

for $f \in S$. The claim then is that the sequence

$$0 \to S \otimes_{\mathbb{Q}_p} A \to (S(f) \otimes_{\mathbb{Q}_p} A) \times (S(f^{-1}) \otimes_{\mathbb{Q}_p} A) \overset{d^0}{\to} S(f, f^{-1}) \otimes_{\mathbb{Q}_p} A \to 0$$

is exact; this follows from the corresponding assertion for $A = \mathbb{Q}_p$, for which see [5 §8.2.3].

From now on, we consider only the strong $G$-topology on $M(S)$.

Definition 3.4. For $A$ a commutative Banach algebra over $\mathbb{Q}_p$, an $A$-module $N$ on $M(S)$ is coherent if there exists an admissible covering $\{M(S_i)\}_{i \in I}$ of $M(S)$ by affinoid subdomains such that for each $i \in I$, we have $N|_{M(S_i)} = \ker(\phi : A^n|_{M(S_i)} \to A^n|_{M(S_i)})$ for some morphism $\phi$ of $A$-modules. By Lemma 3.3 this is equivalent to requiring $N|_{M(S)}$ to be the sheaf associated to some finitely presented $(S_i \otimes_{\mathbb{Q}_p} A)$-module.

Lemma 3.5. Let $A$ be a commutative Banach algebra over $\mathbb{Q}_p$ such that for each Tate algebra $T_n$ over $\mathbb{Q}_p$, $T_n \otimes_{\mathbb{Q}_p} A$ is noetherian. Then for any coherent $A$-module $N$ on $M(S)$, the first Čech cohomology $\check{H}^1(N)$ vanishes.

Proof. As in Lemma 3.3 it suffices to check vanishing of the first Čech cohomology computed on a cover of $M(S)$ of the form

$$M(S) = M(S(f)) \cup M(S(f^{-1}))$$

for some $f \in S$, such that $N$ is represented on each of the two covering subsets by a finite module. For this, we may follow the proof of [5 Lemma 9.4.3/5] verbatim. (The noetherian condition is needed so that the invocation of [5 Proposition 3.7.3/3] within the proof of [5 Lemma 9.4.3/5] remains valid.)

To recover an analogue of Kiehl’s theorem, however, we need an extra condition.

Proposition 3.6. Let $A$ be a commutative Banach algebra over $\mathbb{Q}_p$ such that for each Tate algebra $T_n$ over $\mathbb{Q}_p$, $T_n \otimes_{\mathbb{Q}_p} A$ is noetherian and the map $\text{Spec}(T_n \otimes_{\mathbb{Q}_p} A) \to \text{Spec}(T_n)$ carries $M(T_n \otimes_{\mathbb{Q}_p} A)$ to $M(T_n)$. Then any coherent $A$-module $N$ on $M(S)$ is associated to a finite $(S \otimes_{\mathbb{Q}_p} A)$-module.

Proof. There must exist a finite covering of $M(S)$ by affinoid subdomains $M(S_1), \ldots, M(S_n)$ such that $N|_{M(S_i)}$ is associated to a finite $(S_i \otimes_{\mathbb{Q}_p} A)$-module $N_i$. As in [5 Lemma 9.4.3/6], we may deduce from Lemma 3.5 that for each $m \in M(S_i)$, the map $N(M(S)) \to (N/mN)(M(S_i))$ is surjective. By the hypothesis on $A$, each maximal ideal of $S_i \otimes_{\mathbb{Q}_p} A$ lies over a maximal ideal of $S_i$; we may thus deduce that $N(M(S)) \otimes_S S_i$ surjects onto $N(M(S_i))$. Since the latter is a finite $S_i \otimes_{\mathbb{Q}_p} A$-module, we can choose finitely many elements of $N(M(S))$ which generate all of the $N(M(S_i))$. That is, we have a surjection $A^n \to N$ for some $n$; repeating the argument for the kernel of this map yields the claim.
To use the above argument, we need to prove a variant of the Nullstellensatz; for simplicity, we restrict to the case where $K$ is discretely valued (the case of interest in this paper). We first prove a finite generation result using ideas from the theory of Gröbner bases.

**Lemma 3.7.** Let $K$ be a complete discretely valued field extension of $\mathbb{Q}_p$. Let $A$ be a commutative Banach algebra over $K$ such that $A$ has the same set of nonzero norms as $K$, and the ring $\mathcal{O}_A/I_A$ is noetherian. Then $T_n \hat{\otimes}_{\mathbb{Q}_p} A$ is also noetherian.

*Proof.* Equip the monoid $\mathbb{Z}_{\geq 0}^n$ with the componentwise partial ordering $\leq$ and the lexicographic total ordering $\preceq$. That is, $(x_1, \ldots, x_n) \leq (y_1, \ldots, y_n)$ if $x_i \leq y_i$ for all $i$, whereas $(x_1, \ldots, x_n) \preceq (y_1, \ldots, y_n)$ if there exists an index $i \in \{1, \ldots, n+1\}$ such that $x_j = y_j$ for $j < i$, and either $i = n+1$ or $x_i \leq y_i$. Recall that $\preceq$ is a well partial ordering and that $\preceq$ is a well total ordering; in particular, any sequence in $\mathbb{Z}_{\geq 0}^n$ has a subsequence which is weakly increasing under both orderings.

For $I = (i_1, \ldots, i_n) \in \mathbb{Z}_{\geq 0}^n$, write $t^I$ for $t_1^{i_1} \cdots t_n^{i_n}$. We represent each element $x \in T_n \hat{\otimes}_{\mathbb{Q}_p} A$ as a formal sum $\sum_{I} x^I t^I$ with $x_I \in A$, such that for each $\epsilon > 0$, there exist only finitely many indices $I$ with $|x_I| \leq \epsilon$. For $x$ nonzero, define the degree of $x$, denoted $\deg(x)$, to be the maximal index $I$ under $\preceq$ among those indices maximizing $|x_I|$. Define the leading coefficient of $x$ to be the coefficient $x_{\deg(x)}$.

Let $J$ be any ideal of $T_n \hat{\otimes}_{\mathbb{Q}_p} A$. We apply a Buchberger-type algorithm to construct a generating set $m_1, \ldots, m_k$ for $J$, as follows. Start with the empty list (i.e., $k = 0$). As long as possible, given $m_1, \ldots, m_k$, choose an element $m_{k+1}$ of $J \cap \mathcal{O}_A$ with leading coefficient $a_{k+1}$, for which we cannot choose $I_1, \ldots, I_k \in \mathbb{Z}_{\geq 0}^n$ and $b_1, \ldots, b_k \in \mathcal{O}_A$ satisfying both of the following conditions.

(a) We have $\deg(m_{k+1}) = \deg(m_l t^{i_l})$ whenever $b_l \neq 0$.

(b) We have $a_{k+1} - a_1 b_1 - \cdots - a_k b_k \in I_A$.

In particular, we must have $|a_{k+1}| = 1$.

We claim this process must terminate. Suppose the contrary; then there must exist a sequence of indices $i_1 < i_2 < \cdots$ such that $\deg(m_{i_1}) \leq \deg(m_{i_2}) \leq \cdots$. Then the sequence of ideals $(a_{i_1}, a_{i_1}, a_{i_2}, \ldots)$ in $\mathcal{O}_A/I_A$ must be strictly increasing, but this violates the hypothesis that $\mathcal{O}_A/I_A$ is noetherian. Hence the process terminates.

Let $| \cdot |$ denote the $1$-Gauss norm on $T_n \hat{\otimes}_{\mathbb{Q}_p} A$. We now write each element of $J$ as a linear combination of $m_1, \ldots, m_k$ using a form of the Buchberger division algorithm. Start with some nonzero $x \in J$ and put $x_0 = x$. Given $x_l \in J$, if $x_l = 0$, put $y_{l,1} = \cdots = y_{l,k} = 0$ and $x_{l+1} = 0$. Otherwise, choose $\lambda \in A^*$ with $|\lambda x_l| = 1$. By the construction of $m_1, \ldots, m_k$, there must exist $I_1, \ldots, I_k \in \mathbb{Z}_{\geq 0}^n$ and $b_1, \ldots, b_k \in \mathcal{O}_A$ satisfying conditions (a) and (b) above with $m_{k+1}$ replaced by $\lambda x_l$. Put $y_{l,i} = \lambda^{-1} b_i t^{I_i}$ and $x_{l+1} = x_l - y_{l,1} m_1 - \cdots - y_{l,k} m_k$.

If $|x_{l+1}| = |x_l|$, we must have $\deg(x_{l+1}) < \deg(x_l)$, since $\preceq$ is a well ordering, we must have $|y_{l,1}| < |x_l|$ for some $l' > l$. Since $K$ is discretely valued and $A$ has the same group of nonzero norms as $K$, we conclude that $|x_l| \to 0$ as $l \to \infty$.

Since $|y_{l,1}| \leq |x_l|$, we may set $y_l = \sum_{i=0}^{\infty} y_{l,i}$ to get elements of $T_n \hat{\otimes}_{\mathbb{Q}_p} A$ such that $x = y_1 m_1 + \cdots + y_k m_k$. This proves that $J$ is always finitely generated, so $T_n \hat{\otimes}_{\mathbb{Q}_p} A$ is noetherian. \qed

We next establish an analogue of the Nullstellensatz by combining the previous argument with an idea of Munshi [17].
Lemma 3.8. Take $K$ and $A$ as in Lemma 3.7, but suppose also that the intersection of the nonzero prime ideals of $A$ is zero. Then for any maximal ideal $m$ of $T_n \otimes_{Q_p} A$, the intersection $m \cap A$ is nonzero.

Proof. Suppose on the contrary that $m$ is a maximal ideal of $T_n \otimes_{Q_p} A$ such that $m \cap A = 0$. Since $T_n \otimes_{Q_p} A$ is noetherian by Lemma 3.7, $m$ is closed by [5] Proposition 3.7.2/2]. Hence $m + A$ is also a closed subspace of $T_n \otimes_{Q_p} A$. Let $\psi: T_n \otimes_{Q_p} A \to (T_n \otimes_{Q_p} A)/A$ be the canonical projection; it is a bounded surjective morphism of Banach spaces with kernel $A$. Put $V = \psi(m + A)$; since $m + A = \psi^{-1}(V)$, the open mapping theorem [5, §2.8.1] implies that $V$ is closed. Hence $\psi$ induces a bounded bijective map $m \to V$ between two Banach spaces; by the open mapping theorem again, the inverse of $\psi$ is also bounded.

Using the power series representation of elements of $T_n \otimes_{Q_p} A$, let us represent $(T_n \otimes_{Q_p} A)/A$ as the set of series in $T_n \otimes_{Q_p} A$ with zero constant term. We may then represent $\psi$ as the map that subtracts off the constant term. Define the nonconstant degree of $x \in T_n \otimes_{Q_p} A$ as $\deg'(x) = \deg(\psi(x))$, and define the leading nonconstant coefficient of $x$ to be the coefficient $x_{\deg'(x)}$.

We construct $m_1, \ldots, m_k \in m$ using the following modified Buchberger algorithm. As long as possible, choose an element $m_{k+1}$ of $m \cap O_A$ with nonconstant leading coefficient $a_{k+1}$, for which we cannot choose $I_1, \ldots, I_k \in \mathbb{Z}_{\geq 0}$ and $b_1, \ldots, b_k \in O_A$ satisfying both of the following conditions.

(a) We have $\deg'(m_{k+1}) = \deg'(m_i t^I)$ whenever $b_i \neq 0$.

(b) We have $a_{k+1} - a_1 b_1 - \cdots - a_k b_k \in I_A$.

Again, this algorithm must terminate.

By the hypothesis on $A$, we can choose a nonzero prime ideal $p$ of $A$ not containing the product $a_1 \cdots a_k$. By our earlier hypothesis that $m \cap A = 0$, we have $m \cap p = 0$. Hence $m + p(T_n \otimes_{Q_p} A)$ is the unit ideal, so we can find $x_0 \in p(T_n \otimes_{Q_p} A)$ such that $1 + x_0 \in m$.

We now perform a modified division algorithm. Given $x_l \in p(T_n \otimes_{Q_p} A)$ such that $1 + x_l \in m$, we cannot have $x_l \in A$. We may thus choose $\lambda \in A^\times$ with $|\psi(\lambda x_l)|_l = 1$. By the construction of $m_1, \ldots, m_k$, there must exist $I_1, \ldots, I_k \in \mathbb{Z}_{\geq 0}$ and $b_1, \ldots, b_k \in A$ satisfying conditions (a) and (b) above with $m_{k+1}$ replaced by $\lambda x_l$. Put $y_{l,i} = \lambda^{-1} b_i t^I$ and $x_{l+1} = x_l - y_{l,1} m_1 - \cdots - y_{l,k} m_k$.

As in the proof of Lemma 3.7, we see that $|\psi(x_l)|_l \to 0$ as $l \to \infty$. Since $\psi$ has bounded inverse, we also conclude that $|x_l|_l \to 0$ as $l \to \infty$. However, since $m$ is closed, this yields the contradiction $1 \in m$. We conclude that $m \cap A \neq 0$, as desired. \hfill \Box

This yields the following.

Lemma 3.9. For any Tate algebra $T_n$ over $Q_p$, any rational $s > 0$, and any complete discretely valued field extension $K$ of $Q_p$, $T_n \otimes_{Q_p} \mathcal{E}_K^s$ is noetherian and each of its maximal ideals has residue field which is finite over $K$. In particular, every maximal ideal of $T_n \otimes_{Q_p} \mathcal{E}_K^s$ lies over a maximal ideal of $T_n$.

Proof. The Banach norm on $\mathcal{E}_K^s$ is the maximum of the $p$-adic norm and the norm induced by $w_s$. By enlarging $K$, we may assume that the nonzero values of this norm are all achieved by elements of $K$. In this case, we check that $A = \mathcal{E}_K^s$ satisfies the hypotheses of Lemma 3.8. First, the nonzero norms of elements of $A$ are all realized by units of the form $\lambda t^i$ with $\lambda \in K$ and $i \in \mathbb{Z}$. Second, the residue ring $O_A/I_A$ is isomorphic to a Laurent polynomial ring over a field, which is noetherian. Third, for each nonzero element $x$ of $A$, we can construct $y \in A$ whose Newton polygon has no
slopes in common with that of \( x \); this implies that \( x \) and \( y \) generate the unit ideal (e.g., see [13 §2.6]), so any maximal ideal containing \( y \) fails to contain \( x \). Hence the intersection of the nonzero prime ideals of \( A \) is zero; moreover, the quotient of \( A \) by any nonzero ideal is finite over \( K \). We may thus apply Lemma 3.8 to deduce the claim. \( \square \)

By combining Proposition 3.6 with Lemma 3.9, we deduce the following. (The second assertion follows from the first because for a coherent module, local freeness can be checked at each maximal ideal.)

**Proposition 3.10.** For any \( s > 0 \) and any finite extension \( K \) of \( \mathbb{Q}_p \), for \( A = \mathcal{E}_K^s \), any coherent \( \mathcal{A} \)-module \( V \) on \( M(S) \) is associated to a finite \((S \widehat{\otimes}_{\mathbb{Q}_p} A)\)-module \( V \). Moreover, \( V \) is locally free if and only if \( V \) is.

Using this, we may extend Theorem 2.3 for affinoid algebras, to eliminate the hypothesis requiring a free Galois-stable lattice. We first handle the case where \( V_S \) is itself free.

**Theorem 3.11.** Let \( S \) be an affinoid algebra over \( \mathbb{Q}_p \). Let \( V_S \) be a free \( S \)-linear representation. There exists \( s(V_S) \geq 0 \) such that for \( s \geq s(V_S) \), we may construct a \((S \widehat{\otimes}_{\mathbb{Q}_p} \mathcal{B}_K^s)\)-module \( D_K^{1,s}(V_S) \) satisfying the following conditions.

1. The \((S \widehat{\otimes}_{\mathbb{Q}_p} \mathcal{B}_K^s)\)-module \( D_K^{1,s}(V_S) \) is locally free of rank \( d \).
2. The natural map \( D_K^{1,s}(V_S) \otimes_{S \widehat{\otimes}_{\mathbb{Q}_p} \mathcal{B}_K^s} (S \widehat{\otimes}_{\mathbb{Q}_p} \mathcal{B}_K^{1,s}) \rightarrow V_S \otimes_S (S \widehat{\otimes}_{\mathbb{Q}_p} \mathcal{B}_K^{1,s}) \) is an isomorphism.
3. For any maximal ideal \( m_x \) of \( S \), for \( V_x = V_S \otimes_S (S/m_x) \), the natural map \( D_K^{1,s}(V_S) \otimes_S (S/m_x) \rightarrow D_K^{1,s}(V_x) \) is an isomorphism.
4. The construction is functorial in \( V_S \), compatible with passage from \( K \) to a finite extension, and compatible with Theorem 2.3 in case \( V_S \) admits a Galois-stable free lattice.

**Proof.** Let \( T_S \) be any free \( \mathcal{O}_S \)-lattice in \( V_S \). Since the Galois action is continuous, there exists a finite Galois extension \( L \) of \( K \) such that \( G_L \) carries \( T_S \) into itself. For such \( L \), for \( s \) sufficiently large, \( D_L^{1,s}(V_S) \) is locally free of rank \( d \) by Theorem 2.3. Moreover, it carries an action of \( \text{Gal}(L/K) \). If we restrict scalars on this module back to \( S \widehat{\otimes}_{\mathbb{Q}_p} \mathcal{B}_K^s \), then \( D_K^{1,s}(V_S) \) appears as a direct summand; this summand is then finite projective, hence locally free (since \( T_n \widehat{\otimes}_{\mathbb{Q}_p} \mathcal{E}_K^s \) is noetherian by Lemma 3.9). Moreover, the \( \text{Gal}(L/K) \)-action on \( D_L^{1,s}(V_S) \) allows us to extend the \( \Gamma_L \)-action on \( D_K^{1,s}(V_S) \) to a \( \Gamma_K \)-action. This yields the desired assertions. \( \square \)

**Definition 3.12.** Let \( S \) be an affinoid algebra over \( \mathbb{Q}_p \). Let \( V_S \) be a locally free \( S \)-linear representation; we can then choose a finite covering of \( M(S) \) by affinoid subdomains \( M(S_i) \) such that \( V_i = V_S \otimes_S S_i \) is free over \( S_i \) for each \( i \). We may then apply Theorem 3.11 to \( V_i \) to produce \( D_K^{1,s}(V_i) \) for \( s \) sufficiently large. By Proposition 3.10, these glue to form a finite \((S \widehat{\otimes}_{\mathbb{Q}_p} \mathcal{B}_K^s)\)-module \( D_K^{1,s}(V_S) \), which satisfies the analogues of the assertions of Theorem 3.11. We may then define

\[
D_K^{1,s}(V_S) = D_K^{1,s}(V_S) \otimes_{S \widehat{\otimes}_{\mathbb{Q}_p} \mathcal{B}_K^s} (S \widehat{\otimes}_{\mathbb{Q}_p} \mathcal{B}_K^1),
\]

and this will be an étale \((\varphi, \Gamma)\)-module over \( S \widehat{\otimes}_{\mathbb{Q}_p} \mathcal{B}_K^1 \). The analogue of Proposition 2.7 will also carry over.
Remark 3.13. Gaëtan Chenevier has pointed out that Theorem 3.11 is also an easy consequence of [6, Lemme 3.18]. That lemma implies that for $S$ an affinoid algebra over $\mathbb{Q}_p$ and $V_S$ a locally free $S$-linear representation, there exist an affine formal scheme $\text{Spf}(R)$ of finite type over $\mathbb{Z}_p$ equipped with an isomorphism $R \otimes_{\mathbb{Z}_p} \mathbb{Q}_p \cong S$, and a locally free $R$-linear representation $T_R$ admitting an isomorphism $T_R \otimes_{\mathbb{Z}_p} \mathbb{Q}_p \cong V_S$. This makes it possible to glue the Berger-Colmez theorem by doing so on a suitable formal model of $S$.

4 Local coefficient algebras

We next show that in a restricted setting, it is possible to invert the $(\varphi, \Gamma)$-module functor $D_K^\dagger$.

Definition 4.1. By a coefficient algebra, we mean a commutative Banach algebra $S$ over $\mathbb{Q}_p$ satisfying the following conditions.

(i) The norm on $S$ restricts to the norm on $\mathbb{Q}_p$.

(ii) For each maximal ideal $m$ of $S$, the residue field of $m$ is finite over $\mathbb{Q}_p$.

(iii) The Jacobson radical of $S$ is zero; in particular, $S$ is reduced.

For instance, any reduced affinoid algebra over $\mathbb{Q}_p$ is a coefficient algebra.

By a local coefficient algebra, we will mean a coefficient algebra $S$ of the form $R \otimes_{\mathbb{Z}_p} \mathbb{Q}_p$, where $R$ is a complete noetherian local domain of characteristic 0 with residue field finite over $\mathbb{F}_p$. For instance, if $S$ is a reduced affinoid algebra over $\mathbb{Q}_p$ equipped with the spectral norm, and $R$ is the completion of $\mathcal{O}_S$ at a maximal ideal, then $R \otimes_{\mathbb{Z}_p} \mathbb{Q}_p$ is a local coefficient algebra.

One special property of local coefficient algebras is the following. (Compare the discussion preceding Lemma 2.6)

Proposition 4.2. Let $R$ be a complete noetherian local domain of characteristic 0 with residue field finite over $\mathbb{F}_p$, and let $S$ be the local coefficient algebra $R \otimes_{\mathbb{Z}_p} \mathbb{Q}_p$.

(a) We may naturally identify $(R \hat{\otimes}_{\mathbb{Z}_p} A_K) \otimes_{\mathbb{Z}_p} \mathbb{Q}_p$ with the $p$-adic completion of $S \hat{\otimes}_{\mathbb{Q}_p} B_K^\dagger$.

(b) We may naturally identify $(R \hat{\otimes}_{\mathbb{Z}_p} \tilde{A}_K) \otimes_{\mathbb{Z}_p} \mathbb{Q}_p$ with a subring of the $p$-adic completion of $S \hat{\otimes}_{\mathbb{Q}_p} \tilde{B}_K^\dagger$.

Proof. Let $P_{1,n,s}, P_{2,n,s}, P_{3,n,s}$ denote the completed tensor products $(R/p^n R) \hat{\otimes}_{\mathbb{Z}_p} (A^{\dagger,s}/p^n A^{\dagger,s})$ formed using the following choices for the topologies on the two sides.

- For $P_{1,n,s}$, use on the left side the discrete topology, and on the right side the topology induced by $w_s$.
- For $P_{2,n,s}$, use on the left side the topology induced by $m_R$, and on the right side the topology induced by $w_s$.
- For $P_{3,n,s}$, use on the left side the topology induced by $m_R$, and on the right side the discrete topology.
These constructions relate to our original question as follows. If we take the inverse limit of the $P_{1,n,s}$ as $n \to \infty$, then invert $p$, then take the union over all choices of $s$, we recover $S \widehat{\otimes}_{Q_p} B^\dagger$. If we take the union of the $P_{3,n,s}$ over all choices of $s$, then take the inverse limit as $n \to \infty$, and finally invert $p$, we recover $(R \widehat{\otimes}_{Z_p} A) \otimes_{Z_p} Q_p$.

To establish (a), it thus suffices to check that the natural maps $P_{1,n,s} \to P_{2,n,s}$ and $P_{3,n,s} \to P_{2,n,s}$ are both bijections. Put $A = m_R(R/p^m R)$ and $I = m_R A$. Put $B = A^\dagger s/p^m A^\dagger s$ and choose an ideal of definition $J \subseteq B$ for the topology induced by $w_s$. In this notation, $A$ is $I$-adically complete and separated, and $B$ is $J$-adically complete and separated, and both $A$ and $B$ are flat over $Z_p/p^n Z_p$. Put $C = A \otimes_{Z_p/p^n Z_p} B$. The $IC$-adic completion of $C$ is then the inverse limit over $m$ of the quotients $C/I^m C = (A/I^m A) \otimes_{Z_p/p^n Z_p} B$. Since $B$ is flat over $Z_p/p^n Z_p$ and $A/I^m A$ has finite cardinality, the completeness of $B$ with respect to $J$ implies the completeness of $C/I^m C$ with respect to $J(C/I^m C)$. It follows that $C$ is complete with respect to $IC + JC$, which means that $P_{1,n,s} \to P_{2,n,s}$ is a bijection. Similarly, we may argue that $P_{3,n,s} \to P_{2,n,s}$ is bijective using the fact that $B/J^m B$ is of finite cardinality.

This yields (a). The whole argument carries over in the case of (b) except for the finiteness of $B/J^m B$; hence in this case, we only have that $P_{1,n,s} \to P_{2,n,s}$ is a bijection and $P_{3,n,s} \to P_{2,n,s}$ is injective.

**Theorem 4.3.** Let $S$ be a local coefficient algebra. Let $M_S$ be an étale $(\varphi, \Gamma)$-module over $S \widehat{\otimes}_{Q_p} B^\dagger_K$, and put

$$V_S = (M_S \otimes_{S \widehat{\otimes}_{Q_p} B^\dagger_K} (S \widehat{\otimes}_{Q_p} B^\dagger_K))^{\varphi = 1}.$$  

Then $V_S$ is an $S$-linear representation for which the natural map $D_K^\dagger(V_S) \to M_S$ is an isomorphism.

**Proof.** By Proposition 1.2(a), we may identify the $p$-adic completion of $S \widehat{\otimes}_{Q_p} B^\dagger_K$ with $(R \widehat{\otimes}_{Z_p} A) \otimes_{Z_p} Q_p$. This allows us to define

$$V'_S = (M_S \otimes_{S \widehat{\otimes}_{Q_p} B^\dagger_K} ((R \widehat{\otimes}_{Z_p} A) \otimes_{Z_p} Q_p))^{\varphi = 1}.$$  

By Theorem 2.2, the natural map

$$V'_S \otimes (R \widehat{\otimes}_{Z_p} A) \otimes_{Z_p} Q_p \to M_S \otimes_{S \widehat{\otimes}_{Q_p} B^\dagger_K} ((R \widehat{\otimes}_{Z_p} A) \otimes_{Z_p} Q_p)$$  

is an isomorphism.

By Proposition 1.2(b), we may identify $(R \widehat{\otimes}_{Z_p} A) \otimes_{Z_p} Q_p$ with a subring of the $p$-adic completion of $S \widehat{\otimes}_{Q_p} B^\dagger$. Using this identify, we may argue as in [14, Proposition 1.2.7] to show that $V'_S \subseteq V_S$, which is enough to establish the desired result.  

**5 A lifting argument**

While one cannot invert the functor $D^\dagger_K$ for an arbitrary $S$, one can give a partial result.

**Lemma 5.1.** For any commutative Banach algebra $S$ over $Q_p$, any $s > 0$, and any $x \in S \widehat{\otimes}_{Q_p} B^\dagger, s$, the equation

$$y - \varphi^{-1}(y) = x$$

has a solution $y \in S \widehat{\otimes}_{Q_p} B^\dagger, s$. More precisely, we may choose $y$ such that $v_p(y) \geq v_p(x)$ and $w_s(y) \geq w_s(x).$
Proof. For $S = \mathbb{Q}_p$, the existence of a solution $y \in \mathbf{\bar{B}}$ follows from the fact that $\mathbf{\bar{B}}$ is a complete discretely valued field with algebraically closed residue field. Write $x = \sum_k p^k[x_k]$ and $y = \sum_k p^k[y_k]$. We claim that $y$ can be chosen such that for each $k$,

$$\inf\{v_E(y_{k}) : \ell \leq k\} \geq \inf\{v_E(x_{\ell}) : \ell \leq k\},$$

which yields the desired results. This choice can be made because for any $\overline{x} \in \mathbf{\bar{E}}$, the equation $\overline{y} - \mathbf{\bar{x}}^{1/p} = \overline{y}$ always has a solution $\overline{y} \in \mathbf{\bar{E}}$ with

$$v_E(\overline{y}) \geq \begin{cases} v_E(\overline{x}) \quad &v_E(\overline{x}) \leq 0 \\ pv_E(\overline{x}) \quad &v_E(\overline{x}) > 0. \end{cases}$$

For general $S$, write $x$ as a convergent sum $\sum_i u_i \otimes x_i$ with $u_i \in S$ and $x_i \in \mathbf{\bar{B}}^{1,s}$. For each $i$, let $y_i \in \mathbf{\bar{B}}^{1,s}$ be a solution of $y_i - \varphi^{-1}(y_i) = x_i$ with $w_s(y_i) \geq w_s(x_i)$. Then the sum $y = \sum_i u_i \otimes y_i$ converges with the desired effect.

**Theorem 5.2.** Let $S$ be a commutative Banach algebra over $\mathbb{Q}_p$. Let $M_S$ be a free étale $(\varphi, \Gamma)$-module over $S \otimes_{\mathbb{Q}_p} \mathbf{\bar{B}}^1_K$. Suppose that there exists a basis of $M_S$ on which $\varphi - 1$ acts via a matrix whose entries have positive $p$-adic valuation. Then

$$V_S = (M_S \otimes_{S \otimes_{\mathbb{Q}_p} \mathbf{\bar{B}}^1_K} (S \otimes_{\mathbb{Q}_p} \mathbf{\bar{B}}^1))^{\varphi=1}$$

is a free $S$-linear representation for which the natural map $D_K(V_S) \to M_S$ is an isomorphism.

Proof. Choose a basis of $M_S' = M_S \otimes_{S \otimes_{\mathbb{Q}_p} \mathbf{\bar{B}}^1_K} (S \otimes_{\mathbb{Q}_p} \mathbf{\bar{B}}^1)$ on which $\varphi - 1$ acts via a matrix $A$ whose entries belong to $S \otimes_{\mathbb{Q}_p} \mathbf{\bar{B}}^{1,s}$ for some $s > 0$ and have $p$-adic valuation bounded below by $c > 0$. We may apply Lemma 5.1 to choose a matrix $X$ such that $X$ has entries in $S \otimes_{\mathbb{Q}_p} \mathbf{\bar{B}}^{1,s}$ with $p$-adic valuation bounded below by $c$, $\min_{i,j}\{w_s(X_{i,j})\} \geq \min_{i,j}\{w_s(A_{i,j})\}$, and $X - \varphi^{-1}(X) = A$. We can thus change basis to get a new basis of $M_S'$ on which $\varphi - 1$ acts via the matrix

$$(I_n - \varphi^{-1}(X))^{-1}(I_n + A)(I_n - X) - I_n,$$

whose entries have valuation bounded below by $2c$. If we repeat this process, we get a sequence of matrices $X_1, X_2, \ldots$ such that $w_s(X_i)$ is bounded below, and the $p$-adic valuation of $X_i$ is at least $ci$. It follows that $w_s(X_i)$ tends to infinity for any $s' > s$, so the product $(I_n + X_1)(I_n + X_2)\cdots$ converges in $S \otimes_{\mathbb{Q}_p} \mathbf{\bar{B}}^{1,s'}$ and defines a basis of $M_S'$ fixed by $\varphi$. This proves the claim. □

**Remark 5.3.** The hypothesis about the basis of $M_S$ is needed in Theorem 5.2 for the following reason. For $R$ an arbitrary $F_p$-algebra, if $\varphi$ acts as the identity on $R$ and as the $p$-power Frobenius on $\mathbf{\bar{E}}$, given an invertible square matrix $A$ over $R \otimes_{F_p} \mathbf{\bar{E}}$, we cannot necessarily solve the matrix equation $U^{-1}A\varphi(U) = A$ for an invertible matrix $U$ over $R \otimes_{F_p} \mathbf{\bar{E}}$. For instance, in Chenevier’s example, there is no solution of the equation $\varphi(z) = Yz$.

One may wish to view the collection of isomorphism classes of $(\varphi, \Gamma)$-modules over $R \otimes_{F_p} F_p((\epsilon - 1))$, for $R$ an $F_p$-algebra, as the “$R$-valued points of the moduli space of mod $p$ representations of $G_{\mathbb{Q}_p}$.” To replace $\mathbb{Q}_p$ with $K$, one should replace $F_p((\epsilon - 1))$ with the $H_K$-invariants of its separable closure.
6 Families of \((\varphi, \Gamma)\)-modules and étale models

We would like to turn next from \((\varphi, \Gamma)\)-modules over \(S \hat{\otimes}_{Q_p} B_{K}^\dagger\) to \((\varphi, \Gamma)\)-modules over \(S \hat{\otimes}_{Q_p} B_{\text{rig}, K}^\dagger\). In the absolute case, these have important applications to the study of de Rham representations, as shown by Berger; see for instance [1]. In the relative case, however, they do not form a robust enough category to be useful; it is better to pass to a more geometric notion. For this, we must restrict to the case where \(S\) is an affinoid algebra.

**Definition 6.1.** Let \(K\) be a finite extension of \(Q_p\), and let \(S\) be an affinoid algebra over \(K\). Recall that \(\mathcal{R}_{K}^s\) denotes the ring of Laurent series with coefficients in \(K\) in a variable \(T\) convergent on the annulus \(0 < v_p(T) \leq 1/s\), and that \(\mathcal{R}_K = \bigcup_{s > 0} \mathcal{R}_{K}^s\). By a vector bundle over \(S \hat{\otimes}_{K} \mathcal{R}_{K}\), we will mean a coherent locally free sheaf over the product of this annulus with \(M(S \otimes_K K)\) in the category of rigid analytic spaces over \(K\). (In case \(S\) is disconnected, we insist that the rank be constant, not just locally constant.) By a vector bundle over \(S \hat{\otimes}_{K} \mathcal{R}_{K}\), we will mean an object in the direct limit as \(s \to \infty\) of the categories of vector bundles over \(S \hat{\otimes}_{Q_p} \mathcal{R}_{K}^s\).

Recall that for \(s\) sufficiently large, we can produce an isomorphism \(B_{\text{rig}, K}^\dagger_s \cong \mathcal{R}_{K_0}^s\). We thus obtain the notion of a vector bundle over \(S \hat{\otimes}_{Q_p} B_{\text{rig}, K}^\dagger_s\), dependent on the choice of the isomorphism. However, the notion of a vector bundle over \(S \hat{\otimes}_{Q_p} B_{\text{rig}, K}^\dagger\) does not depend on any choices.

**Remark 6.2.** For \(S = K\) discretely valued, every vector bundle over \(\mathcal{R}_{K}^s\) is freely generated by global sections [12, Theorem 3.4.1]. On the other hand, for \(S\) an affinoid algebra over \(Q_p\), we do not know whether any vector bundle over \(S \hat{\otimes}_{Q_p} \mathcal{R}_{K}^s\) is \(S\)-locally free; this does not follow from the work of Lütkebohmert [15], which only applies to closed annuli.

**Definition 6.3.** Let \(K\) be a finite extension of \(Q_p\), and let \(S\) be an affinoid algebra over \(Q_p\). By a family of \((\varphi, \Gamma)\)-modules over \(S \hat{\otimes}_{Q_p} B_{\text{rig}, K}^\dagger\), we will mean a vector bundle \(V\) over \(S \hat{\otimes}_{Q_p} B_{\text{rig}, K}^\dagger\) equipped with an isomorphism \(\varphi^*V \to V\), viewed as a semilinear \(\varphi\)-action, and a semilinear \(\Gamma\)-action commuting with the \(\varphi\)-action. We say a family of \((\varphi, \Gamma)\)-modules over \(S \hat{\otimes}_{Q_p} B_{\text{rig}, K}^\dagger\) is étale if it arises by base extension from an étale \((\varphi, \Gamma)\)-module over \(S \hat{\otimes}_{Q_p} B_{K}^\dagger\); we call the latter an étale model of the family.

It turns out that étale models are unique when they exist. To check this without any reducedness hypothesis on \(S\), we need a generalization of the fact that a reduced affinoid algebra embeds into a product of complete fields [1, Proposition 2.4.4].

**Lemma 6.4.** Let \(K\) be a finite extension of \(Q_p\), and let \(S\) be an affinoid algebra over \(Q_p\). Then there exists a strict inclusion \(S \to \prod_{i=1}^n A_i\) of topological rings, in which each \(A_i\) is a finite connected algebra over a complete discretely valued field.

**Proof.** Let \(T\) be the multiplicative subset of \(O_S\) consisting of elements whose images in \(O_S/I_S\) are not zero divisors. For any \(s \in S\) and \(t \in T\), we have \(|st| = |s||t|\), so the norm on \(S\) extends uniquely to the localization \(S[1/T^{-1}]\). The completion of this localization has the desired form. \(\Box\)

**Proposition 6.5.** Let \(K\) be a finite extension of \(Q_p\), and let \(S\) be an affinoid algebra over \(Q_p\). Then the natural base change functor from étale \((\varphi, \Gamma)\)-modules over \(S \hat{\otimes}_{Q_p} B_{K}^\dagger\) to families of \((\varphi, \Gamma)\)-modules over \(S \hat{\otimes}_{Q_p} B_{\text{rig}, K}^\dagger\) is fully faithful. In fact, this holds even without the \(\Gamma\)-action.
Proof. Note that if we replace $S$ by a complete discretely valued field $L$, we may deduce the analogous claim by [13, Theorem 6.3.3] after translating notations. (We must note that families of $(\varphi, \Gamma)$-modules over $B_{\text{rig}, K}^\dagger$ are finite free over $B_{\text{rig}, K}^\dagger$ by Remark [6.2].) In fact, if we replace $S$ by a finite algebra over $L$, we may make the same deduction by restricting scalars to $L$. We may thus deduce the original claim by embedding $S$ into a product of finite algebras over complete discretely valued fields using Lemma [6.4]. \hfill \square

**Corollary 6.6.** Let $K$ be a finite extension of $\mathbb{Q}_p$, and let $S$ be an affinoid algebra over $\mathbb{Q}_p$. Then an étale model of a family of $(\varphi, \Gamma)$-modules over $S \otimes_{\mathbb{Q}_p} B_{\text{rig}, K}^\dagger$ is unique if it exists.

**Definition 6.7.** Let $S$ be an affinoid algebra over $\mathbb{Q}_p$. Let $V_S$ be a locally free $S$-linear representation. We define $D^\dagger_K(V_S)$ as in Definition [3.12] then put

$$D^\dagger_{\text{rig}, K}(V_S) = D^\dagger_K(V_S) \otimes_{S \otimes_{\mathbb{Q}_p} B_K^\dagger} (S \otimes_{\mathbb{Q}_p} B_{\text{rig}, K}^\dagger).$$

This is an étale $(\varphi, \Gamma)$-module over $S \otimes_{\mathbb{Q}_p} B_{\text{rig}, K}^\dagger$, from which we may recover $V_S$ by taking

$$V_S = (D^\dagger_{\text{rig}, K}(V_S) \otimes_{S \otimes_{\mathbb{Q}_p} B_{\text{rig}, K}^\dagger} (S \otimes_{\mathbb{Q}_p} B_{\text{rig}}^\dagger))^{\varphi=1}.$$ 

We may now obtain Theorem of the introduction by combining Theorem [4.3](via Definition [3.12]) with Proposition [6.5].

### 7 Local étaleness

We now turn to Theorem [0.2] of the introduction. Given what we already have proven, this can be obtained by invoking some results from [16]. For the convenience of the reader, we recall these results in detail.

**Lemma 7.1.** Let $K$ be a finite extension of $\mathbb{Q}_p$, and let $S$ be an affinoid algebra over $K$. For any $x \in M(S)$ and $\lambda > 0$, there exists an affinoid subdomain $M(B)$ of $M(S)$ containing $x$ such that if $f \in S$ vanishes at $x$, then $|f(y)| \leq \lambda |f|_S$ for any $y \in M(B)$.

**Proof.** We first prove the lemma for $S = T_n = K(x_1, \ldots, x_n)$, the $n$-dimensional Tate algebra over $K$. It is harmless to enlarge $K$, so we may suppose without loss of generality that $x$ is the origin $x_1 = \cdots = x_n = 0$. Choosing a rational number $\lambda' < \lambda$, the affinoid subdomain $\{(x_1, \ldots, x_n) \in M(S) : |x_1| \leq \lambda', \ldots, |x_n| \leq \lambda'\}$ satisfies the required property.

For general $S$, the reduction $\overline{S} = \mathcal{O}_S/m_K \mathcal{O}_S$ is a finite type scheme over the residue field $k$ of $K$. For $n$ sufficiently large, we take a surjective $k$-algebra homomorphism $\overline{x} : k[\overline{x}_1, \ldots, \overline{x}_n] \to \overline{S}$. We lift $\overline{x}$ to a $K$-affinoid algebra homomorphism $\alpha : K(x_1, \ldots, x_n) \to S$ by mapping $x_i$ to a lift of $\overline{x}(x_i)$ in $\mathcal{O}_S$. Then it follows from Nakayama’s lemma that $\alpha$ maps $\mathcal{O}_K(x_1, \ldots, x_n)$ onto $\mathcal{O}_S$. Let $\alpha$ also denote the induced map from $M(S)$ to $M(K(x_1, \ldots, x_n))$. By the case of $K(x_1, \ldots, x_n)$, we can find an affinoid neighborhood $M(B)$ of $\alpha(x)$ satisfying the required property for $\lambda/p$. Now for any nonzero $f \in S$ vanishing at $x$, we choose $c \in \mathbb{Q}_p$ such that $|c| \leq |f|_S \leq p|c|$, yielding $pf/c \in \mathcal{O}_S$. Pick $f' \in \mathcal{O}_K(x_1, \ldots, x_n)$ such that $\alpha(f') = pf/c$. Then $f'(\alpha(x)) = (pf/c)(x) = 0$ implies that $|f'(y)| \leq (\lambda/p)|f'|_{T_n} \leq \lambda/p$ for any $y \in M(B)$. Then for any $y \in \alpha^{-1}(M(B))$, we have $|pf(y)|/|c| = |f'(\alpha(y))| \leq \lambda/p$, yielding $|f(y)| \leq \lambda|c| \leq \lambda|f|_S$. Hence $\alpha^{-1}(M(B))$ is an affinoid neighborhood of $x$ satisfying the property we need. \hfill \square
Definition 7.2. For $S$ a commutative Banach algebra over $\mathbb{Q}_p$ and $I$ a subinterval of $\mathbb{R}$, let $\mathcal{R}^I_S$ be the ring of Laurent series over $S$ in the variable $T$ convergent for $v(T)^{-1} \in I$. Let $v_S$ be the valuation on $S$, and for $s \in I$ and $x = \sum_i x_i T^i \in \mathcal{R}^I_S$ put
\[
  w_s(x) = \inf_i \{i + sv_S(x_i)\}.
\]

Put $\mathcal{R}^s_S = \mathcal{R}^{[s, +\infty)}_S$, which we may identify with the completed tensor product $S \hat{\otimes}_{\mathbb{Q}_p} \mathcal{R}^s_{\mathbb{Q}_p}$ for the Fréchet topology on the right, and put $\mathcal{R}_S = \cup_{s > 0} \mathcal{R}^s_S$. Let $\mathcal{R}^{\text{int}, s}_S$ be the subring of $\mathcal{R}^s_S$ consisting of series with coefficients in $O_S$.

The following lemma is based on [13] Lemma 6.1.1].

Lemma 7.3. Let $K$ be a finite extension of $\mathbb{Q}_p$, and let $S$ be an affinoid algebra over $K$. Pick $s_0 > 0$. Let $\varphi : \mathcal{R}^{s_0/p}_S \to \mathcal{R}^{s_0}_S$ be a map of the form $\sum_i c_i T^i \mapsto \sum_i \phi_S(c_i) W^i$, where $\phi_S : S \to S$ is an isometry and $W \in \mathcal{R}^{s_0}_S$ satisfies $w_{s_0}(W - T^p) > w_{s_0}(T^p)$. For some $s \geq s_0$, let $D$ be an invertible $n \times n$ matrix over $\mathcal{R}^{[s, s]}_S$, and put $h = -w_s(D) - w_s(D^{-1})$; it is clear that $h \geq 0$. Let $F$ be an $n \times n$ matrix over $\mathcal{R}^{[s, s]}_S$ such that $w_s(F D^{-1} - I_n) \geq c + h/(p - 1)$ for a positive number $c$. Then for any positive integer $k$ satisfying $2(p - 1)k s \leq c$, there exists an invertible $n \times n$ matrix $U$ over $\mathcal{R}^{[s/p, s]}_S$ such that $U^{-1} F \varphi(U) D^{-1} - I_n$ has entries in $p^k \mathcal{R}^{\text{int}, s}_S$ and $w_s(U^{-1} F \varphi(U) D^{-1} - I_n) \geq c + h/(p - 1)$.

Proof. For $i \in \mathbb{R}$, $s > 0$, $f = \sum_{j=-\infty}^{+\infty} a_j T^j \in \mathcal{R}_S$, we set $v_i(f) = \min\{j : v_S(a_j) \leq i\}$ and $v_{i, s}(f) = v_i(f) + si$. It is clear that $v_{i, s}(f) \geq w_s(f)$. (In case $S$ is a field, these are similar to the quantities $v_{i, \text{naive}}, v_{i, \text{naive}}$ in [13] p. 458, albeit with a slightly different normalization.)

We define a sequence of invertible matrices $U_0, U_1, \ldots$ over $\mathcal{R}^{[s/p, s]}_S$ and a sequence of matrices $F_0, F_1, \ldots$ over $\mathcal{R}^{[s, s]}_S$ as follows. Set $U_0 = I_n$. Given $U_i$, put $F_i = U_i^{-1} F \varphi(U_i)$. Suppose $F_i D^{-1} - I_n = \sum_{m=-\infty}^{+\infty} V_m T^m$ where the $V_m$’s are $n \times n$ matrices over $S$. Let $X_i = \sum_{v_S(V_m) < k} V_m T^m$, and put $U_{i+1} = U_i(I_n + X_i)$. Set
\[
  c_l = \inf_{i \leq k - 1} \{v_{i, s}(F_i D^{-1} - I_n) - h/(p - 1)\}.
\]

We now prove by induction that $c_l \geq \frac{l+1}{2} c$, $w_s(F_l D^{-1} - I_n) \geq c + h/(p - 1)$ and $U_l$ is invertible over $\mathcal{R}^{[s/p, s]}_S$ for any $l \geq 0$. This is obvious for $l = 0$. Suppose that the claim is true for some $l \geq 0$. Then for any $t \in [s/p, s]$, since $c_l \geq \frac{l+1}{2} c \geq (p - 1) s k$, we have
\[
  w_t(X_l) \geq w_s(X_l) - (s - t) k \geq (c_l + h/(p - 1)) - (s - t) k > 0.
\]

Hence $U_{l+1}$ is also invertible over $\mathcal{R}^{[s/p, s]}_S$. Furthermore, we have
\[
  w_s(D \varphi(X_l) D^{-1}) \geq w_s(D) + w_s(\varphi(X_l)) + w_s(D^{-1})\]
\[
  = p w_{s/p}(X_l) - h\]
\[
  \geq p(c_l + h/(p - 1)) - h - (p - 1) s k\]
\[
  = p c_l + h/(p - 1) - (p - 1) s k\]
\[
  \geq c_l + \frac{1}{2} c + h/(p - 1) + \left(\frac{1}{2} c - (p - 1) s k\right)\]
\[
  \geq \frac{(l+2)}{2} c + h/(p - 1).
\]
Since $c_l \geq \frac{l+1}{2}c$ by inductive assumption. Note that

$$F_{l+1}D^{-1} - I_n = (I_n + X_l)^{-1}F_lD^{-1}(I_n + D\varphi(X_l)D^{-1}) - I_n$$

$$= ((I_n + X_l)^{-1}F_lD^{-1} - I_n) + (I_n + X_l)^{-1}(F_lD^{-1})D\varphi(X_l)D^{-1}.$$ 

Since $w_s(F_lD^{-1}) \geq 0$ and $w_s((I_n + X_l)^{-1}) \geq 0$, we have $w_s((I_n + X_l)^{-1}(F_lD^{-1})D\varphi(X_l)D^{-1}) \geq \frac{(l+2)}{2}c + h/(p-1)$. Write

$$(I_n + X_l)^{-1}F_lD^{-1} - I_n = (I_n + X_l)^{-1}(F_lD^{-1} - I_n - X_l)$$

$$= \sum_{j=0}^{\infty}(-X_l)^j(F_lD^{-1} - I_n - X_l).$$

For $j \geq 1$, we have

$$w_s((-X_l)^j(F_lD^{-1} - I_n - X_l)) \geq c + c_l + 2h/(p-1) > \frac{l+2}{2}c + h/(p-1).$$

By the definition of $X_l$, we also have $v_i(F_lD^{-1} - I_n - X_l) = \infty$ for $i < k$ and $w_s(F_lD^{-1} - I_n - X_l) \geq c + h/(p-1)$. Putting these together, we get that

$$v_{i,s}(F_{l+1}D^{-1} - I_n) \geq \frac{l+2}{2}c + h/(p-1)$$

for any $i < k$, i.e., $c_{l+1} \geq \frac{l+2}{2}c$, and that $w_s(F_{l+1}D^{-1} - I_n) \geq c + h/(p-1)$. The induction step is finished.

Now since $w_l(X_l) \geq c_l + h/(p-1) - (p-1)ps/k$ for $t \in [s/p,s]$, and $c_l \to \infty$ as $l \to \infty$, the sequence $U_l$ converges to a limit $U$, which is an invertible $n \times n$ matrix over $R_S^{[s/p,s]}$ satisfying $w_s(U^{-1}F\varphi(U)D^{-1} - I_n) \geq c + h/(p-1)$. Furthermore, we have

$$v_{m,s}(U^{-1}F\varphi(U)D^{-1} - I_n) = \lim_{l \to \infty} v_{m,s}(U_l^{-1}F_l\varphi(U_l)D^{-1} - I_n) = \lim_{l \to \infty} v_{m,s}(F_{l+1}D^{-1} - I_n) = \infty,$$

for any $m < k$. Therefore $U^{-1}F\varphi(U)D^{-1} - I_n$ has entries in $p^k R_S^{\text{int},s}$.

\[\square\]

**Theorem 7.4.** Let $S$ be an affinoid algebra over $\mathbb{Q}_p$, and let $M_S$ be a family of $(\varphi, \Gamma)$-modules over $S \otimes_{\mathbb{Q}_p} B_{\text{rig}, K}^1$, such that for some $x \in M(S)$ whose residue field is contained in $S$, the fibre $M_x$ of $M_S$ over $x$ is étale. Then there exists an affinoid neighborhood $M(B)$ of $x$ and a finite extension of $L$ of $K$ such that the base extension $M_B$ of $M_S$ to $B \otimes_{\mathbb{Q}_p} B_{\text{rig}, L}^1$ has an étale model in which the entries of the matrix of $\varphi - 1$ have positive $p$-adic valuation.

**Proof.** Because Proposition 6.5 does not require the $\Gamma$-action, it suffices to construct an étale model just for the $\varphi$-action. Choose an isomorphism $B_{\text{rig}, K}^{1,s_0} \cong R_{K_0}^{s_0}$ for some $s_0 > 0$, via which $\varphi$ induces a map from $R_{K_0}^{s_0/p}$ to $R_{K_0}^{s_0}$ satisfying $w_{s_0}(\varphi(T) - T^p) > w_{s_0}(T^p)$. Then choose $s \geq s_0$ such that $M_S$ is represented by a vector bundle $V_S$ over $S \otimes_{\mathbb{Q}_p} R_{K_0}^{s_0/p}$ equipped with an isomorphism $\varphi^*V_S \to V_S$ of vector bundles over $S \otimes_{\mathbb{Q}_p} R_{K_0}^{s_0}$.

By hypothesis, $M_x$ is étale. After increasing $s$, we may thus assume that $M_x$ admits a basis $e_x$ on which $\varphi$ acts via an invertible matrix over $R_{K_0}^{s_0/m_x}$. Lift this matrix to a matrix $D$ over $R_{S/m_x}^{\text{int},s}$, using the inclusion $S/m_x \to S$ which was assumed to exist. By enlarging $K$, we can ensure that $D - 1$ has positive $p$-adic valuation (by first doing so modulo $m_x$).
By results of Lütkebohmert [15, Satz 1, 2], the restriction of $V_S$ to $S \otimes_{\Q_p} \mathcal{R}_{K_0}^{[s/p,s]}$ is $S$-locally free. By replacing $M(S)$ with an affinoid subdomain containing $x$, we may reduce to the case where this restriction admits a basis $e_S$. Let $A$ be the matrix via which $\varphi$ acts on this basis; it has entries in $S \otimes_{\Q_p} \mathcal{R}_{K_0}^{[s,s]}$. Let $V$ be a matrix over $S \otimes_{\Q_p} \mathcal{R}_{K_0}^{[s/p,s]}$ lifting (again using the inclusion $S/\mathfrak{m}_x \hookrightarrow S$) the change-of-basis matrix from the mod-$\mathfrak{m}_x$ reduction of $e_S$ to $e_x$.

By Lemma [7.3] we can shrink $S$ so as to make $D$ invertible over $\mathcal{R}_{S}^{\text{int},s}$. We can also force $V$ to become invertible, and we may make $V^{-1}A\varphi(V) - D$ as small as desired. We may thus put ourselves in position to apply Lemma [7.3] with $F = V^{-1}A\varphi(V)$, to produce an invertible $n \times n$ matrix $U$ over $S \otimes_{\Q_p} \mathcal{R}_{K_0}^{[s/p,s]}$ such that $W = U^{-1}F\varphi(U)D^{-1} - I_n$ has entries in $p\mathcal{O}_S \otimes_{\Z_p} \mathcal{R}_{K_0}^{\text{int},s}$ and $w_s(W) > 0$.

Changing basis from $e_S$ via the matrix $VU$ gives another basis $e'_S$ of $V_S$ over $S \otimes_{\Q_p} \mathcal{R}_{K_0}^{[s/p,s]}$, on which $\varphi$ acts via the matrix $(W + I_n)D$. We may change basis $e'_S$ using $(W + I_n)D$ to get a new basis of $V_S$ over $S \otimes_{\Q_p} \mathcal{R}_{K_0}^{[s,s,ps]}$; since $(W + I_n)D$ is invertible over $\mathcal{O}_S \otimes_{\Z_p} \mathcal{R}_{K_0}^{\text{int},s}$, the basis $e'_S$ also generates $V_S$ over $S \otimes_{\Q_p} \mathcal{R}_{K_0}^{[s,ps]}$. Repeating the argument, we deduce that $e'_S$ is actually a basis of $V_S$ generating an étale model. This proves the claim.

Combining Theorem [5.2] with Theorem [7.4] yields Theorem 0.2. Note that before applying Theorem [7.4] we must first extend scalars from $S$ to $S \otimes_{\Q_p} L$ for $L = S/\mathfrak{m}_x$; we then use Galois descent for the action of $\text{Gal}(L/\Q_p)$ to recover a statement about $S$ itself.

**Remark 7.5.** Unfortunately, there is no natural extension of Theorem [7.4] to the Berkovich analytic space $\mathcal{M}(S)$ associated to $S$. For instance, take $K = \Q_p$, $S = \Q_p(y)$, and let $M_S$ be free of rank 2 with the action of $\varphi$ given by the matrix

$$
\begin{pmatrix}
0 & 1 \\
1 & y/p
\end{pmatrix}
$$

(in which $T$ does not appear). The locus of $x \in M(S)$ where $M_x$ is étale is precisely the disc $|y| \leq |p|$, which does not correspond to an open subset of $\mathcal{M}$.

On the other hand, it may still be the case that $M_S$ is étale if and only if $M_x$ is étale (in an appropriate sense) for each $x \in \mathcal{M}(S)$.

**Remark 7.6.** It should be possible to generalize Berger’s construction in [2] to families of filtered $(\phi,N)$-modules. With such a generalization, one would deduce immediately from Theorem [7.4] that any family of weakly admissible $(\phi,N)$-modules over an affinoid base (with trivial $\phi$-action on the base) arises from a Galois representation in a neighborhood of any given rigid analytic point. However, in view of Remark [7.5] we cannot make the corresponding assertion for Berkovich points.

**Remark 7.7.** The families of $(\varphi,\Gamma)$-modules considered here are “arithmetic” in the sense that $\varphi$ acts trivially on the base $S$. They correspond to “arithmetic” families of Galois representations, such as the $p$-adic families arising in the theory of $p$-adic modular forms. There is also a theory of “geometric” families of $(\varphi,\Gamma)$-modules, in which $\varphi$ acts as a Frobenius lift on the base $S$. These correspond to representations of arithmetic fundamental groups via the work of Faltings, Andreatta, Brinon, Iovita, et al. In the latter theory, one does expect the étale locus to be open, as in Hartl’s work [11, Theorem 5.2]. One also expects that a family of $(\varphi,\Gamma)$-modules is globally étale if and only if it is étale over each Berkovich point (but not if it is only étale over each rigid point, as shown by the Rapoport-Zink spaces). We hope to consider this question in subsequent work.
