Measurement of the $\bar{t}t$ production cross section in pp collisions at $\sqrt{s} = 7$ TeV in dilepton final states containing a $\tau$

S. Chatrchyan et al.*
(CMS Collaboration)
(Received 30 March 2012; published 19 June 2012)

The top quark pair production cross section is measured in dilepton events with one electron or muon, and one hadronically decaying $\tau$ lepton from the decay $\bar{t}t \rightarrow (\ell\nu\ell)(\tau_b\nu\tau)$, where $\ell = e, \mu$. The data sample corresponds to an integrated luminosity of 2.0 fb$^{-1}$ for the electron channel and 2.2 fb$^{-1}$ for the muon channel, collected by the CMS detector at the LHC. This is the first measurement of the $\bar{t}t$ cross section explicitly including $\tau$ leptons in proton-proton collisions at $\sqrt{s} = 7$ TeV. The measured value $\sigma_{\bar{t}t} = 143 \pm 14$(stat) $\pm 22$(syst) $\pm 3$(lumi) pb is consistent with the standard model predictions.

I. INTRODUCTION

Top quarks at the Large Hadron Collider (LHC) are mostly produced in pairs with the subsequent decay. The decay modes of the two W bosons determine the observed event signature. The dilepton decay channel denotes the case where both $W$ bosons from the decaying top quark pair decay leptonically. In this Letter, top quark decays in the “tau dilepton” channel are studied, where one $W$ boson decays into $e\nu$ or $\mu\nu$ and the other into the hadronically decaying $\tau$ lepton and $\nu$, in the final state $\bar{t}t \rightarrow (\ell\nu\ell)(\tau_b\nu\tau)$, where $\ell = e, \mu$. The expected fraction of events in the dilepton channel with at least one $\tau$ lepton in the final state is approximately 6% (5/81) of all $\bar{t}t$ decays, i.e. higher than the fraction of the light dilepton channels ($ee, \mu\mu, e\mu$) which is equal to 4/81 of all $\bar{t}t$ decays. The tau dilepton channel is of particular interest because the existence of a charged Higgs boson [1,2] with a mass smaller than the top quark mass could give rise to anomalous $\tau$ lepton production, which could be directly observable in this decay channel. Furthermore, in the final state studied, the $t \rightarrow (\tau\nu\tau)b$ decay exclusively involves third generation leptons and quarks. Understanding the $\tau$ yield in top quark decays is important to increase the acceptance for $\bar{t}t$ events and to search for new physics processes.

This is the first measurement of the $\bar{t}t$ production cross section at the LHC that explicitly includes $\tau$ leptons, improving over the results obtained at the Tevatron which are limited by the small number of candidate events found [3–5]. Experimentally, the $\tau$ lepton is identified by its decay products, either hadrons ($\tau_h$) or leptons ($\tau_{\ell}$), with the corresponding branching fractions $Br(\tau_h \rightarrow \text{hadrons} + \nu_\tau) \approx 65\%$ and $Br(\tau_{\ell} \rightarrow \ell\nu\ell\nu_{\tau}, \ell = e, \mu) \approx 35\%$. In the first case, a narrow jet with a distinct signature is produced; in the case of leptonic decays, the distinction from prompt electron or muon production is experimentally difficult, consequently only hadronic $\tau$ decays are studied here. The cross section is measured by counting the number of $e\tau_h + X$ and $\mu\tau_h + X$ events consistent with originating from $\bar{t}t$, subtracting the contributions from other processes, and correcting for the efficiency of the event selection. The measurement is based on data collected by the Compact Muon Solenoid (CMS) experiment in 2011. The integrated luminosity of the data samples are 1.99 fb$^{-1}$ and 2.22 fb$^{-1}$ for the $e\tau_h$ and $\mu\tau_h$ final states, respectively.

The CMS detector is briefly summarized in Sec. II, details of the simulated samples are given in Sec. III, a brief description of the event reconstruction and event selection is provided in Sec. IV, followed by the description of the background determination and systematic uncertainties in Secs. V and VI, respectively. The measurement of the cross section is discussed in Sec. VII, and the results are summarized in Sec. VIII.

II. THE CMS DETECTOR

The central feature of the CMS apparatus is a superconducting solenoid, 13 m in length and 6 m in diameter, which provides an axial magnetic field of 3.8 T. Inside the solenoid, various particle detection systems are employed. Charged particle trajectories are measured by the silicon pixel and strip tracker, covering 0 $< \varphi < 2 \pi$ in azimuth and $|\eta| < 2.5$, where the pseudorapidity $\eta$ is defined as $\eta = -\ln[\tan(\theta/2)]$, with $\theta$ being the polar angle of the trajectory of the particle with respect to the counterclockwise beam direction. A crystal electromagnetic calorimeter and a brass/scintillator hadron calorimeter surround the tracking volume; in this analysis the calorimetry provides high-resolution energy and direction measurements of electrons and hadronic jets. Muon detection systems are located outside of the solenoid and embedded in the steel return yoke. The detector is nearly hermetic, allowing for energy balance measurements in the plane transverse to the

A two-level trigger system selects the most interesting proton-proton collision events for use in physics analysis. A more detailed description of the CMS detector can be found elsewhere [6].

### III. EVENT SIMULATION

The analysis makes use of simulated samples of $t\bar{t}$ events as well as other processes that result in $t\bar{t}$ in the final state. These samples are used to design the event selection, to calculate the acceptance to $t\bar{t}$ events, and to estimate some of the backgrounds in the analysis.

Signal $t\bar{t}$ events are simulated with the MADGRAPH event generator (v. 5.1.1.0) [7] with matrix elements corresponding to up to three additional partons, for a top quark mass of 172.5 GeV/$c^2$. The number of expected $t\bar{t}$ events is estimated with the approximate next-to-next-to-leading order (NNLO) expected standard model (SM) cross section value of $165^{+38}_{-32}(\text{scale})^{\pm 0.7}(\text{PDF})$ pb [8,9], where the first uncertainty is due to renormalization and factorization scales, and the second is due to the parton distribution function (PDF) uncertainty. This cross section is used for illustrative purposes to normalize the $t\bar{t}$ events and $\mu\tau_\nu$ expectations discussed in Section IV. The generated events are subsequently processed with PYTHIA (v. 6.422) [10] to provide the showering of the partons, and to perform the matching of the soft radiation with the contributions from direct emissions accounted for in the matrix-element calculations. The Z2 tune [11] is used with the CTEQ6L PDFs [12]. The $\tau$ decays are simulated with TAUOLA (v. 27.121.5) [13] which correctly accounts for the $\tau$ lepton polarization in describing the decay kinematics. The CMS detector response is simulated with GEANT4 (v. 9.3 Rev01) [14].

The background samples used in the measurement of the cross section are simulated with MADGRAPH and PYTHIA. The $W + $jet samples include only the leptonic decays of the boson, and are normalized to the inclusive next-to-next-leading-order (NNLO) cross section of $31.3 \pm 1.6$ nb, calculated with the FEWZ (Fully Exclusive $W$ and $Z$ boson) production program [15]. Drell–Yan (DY) pair production of charged leptons in the final state is generated with MADGRAPH for dilepton invariant masses above 50 GeV/$c^2$, and is normalized to a cross section of $3.04 \pm 0.13$ nb, computed with FEWZ. The DY events with masses between 10 and 50 GeV/$c^2$ are generated with MADGRAPH with a cross section (with a $k$-factor of 1.33 to correct for NLO) of 12.4 nb.

The electroweak production of single top quarks is considered as a background process, and is simulated with POWHEG [16]. The $t$-channel single top quark NLO cross section is $\sigma_{tch} = 64.6^{+3.4}_{-3.2}$ pb from MCFM [17–20]. The single top quark associated production ($tW$) cross section amounts to $\sigma_{tW} = 15.7 \pm 1.2$ pb [21]. The $s$-channel single top quark next-to-next-leading-log (NNLL) cross section is determined as $\sigma_{s\chi} = 4.6 \pm 0.06$ pb [22]. Finally, the production of $WW$, $WZ$, and $ZZ$ pairs, with inclusive cross sections of $43.0 \pm 1.5$ pb, $18.8 \pm 0.7$ pb, and $7.4 \pm 0.2$ pb, respectively (all calculated at the NLO with MCFM), are simulated with PYTHIA.

### IV. EVENT SELECTION

The signal topology is defined by the presence of two $b$ jets from the top quark decays, one $W$ boson decaying leptonically into $e\nu$ or $\mu\nu$, and a second boson decaying into $\tau\nu$. In the event, all objects are reconstructed with a particle-flow (PF) algorithm [23]. The PF algorithm combines the information from all subdetectors to identify and reconstruct all types of particles produced in the collision, namely, charged hadrons, photons, neutral hadrons, muons, and electrons. The resulting list of particles is used to construct a variety of higher-level objects and observables such as jets, missing transverse energy ($E_T^{\text{miss}}$), leptons (including $t\bar{t}$), photons, $b$-tagging discriminators, and isolation variables. The missing transverse energy $E_T^{\text{miss}}$ is computed as the absolute value of the vectorial sum of the transverse momenta of all reconstructed particles in the event.

Electron or muon candidates are required to be isolated relative to other activity in the event. The relative isolation is based on PF objects and defined as $I_{\text{rel}} = (E_{\text{ch}} + E_{\text{nh}} + E_{\text{ph}})/p_T \cdot c$, where $E_{\text{ch}}$ is the transverse energy deposited by charged hadrons in a cone of radius $\Delta R = 0.3$ around the electron or muon track, $E_{\text{nh}}$ and $E_{\text{ph}}$ are the respective transverse energies of the neutral hadrons and photons, and $p_T$ is the electron or muon transverse momentum. The electron (muon) candidate is considered to be non-isolated and is rejected if $I_{\text{rel}} > 0.1(>0.2)$. Jets are reconstructed with the anti-$k_T$ [24,25] jet algorithm with a distance parameter $R = 0.5$.

Hadronic $\tau$ decays are reconstructed with the Hadron Plus Strips (HPS) algorithm [26]. The identification process starts with the clustering of all PF particles into jets with the anti-$k_T$ algorithm with a distance parameter $R = 0.5$. For each jet, a charged hadron is combined with other nearby charged hadrons or photons to identify the decay modes. The identification of $\pi^0$ mesons is enhanced by clustering electrons and photons in “strips” along the bending plane to take into account possible broadening of calorimeter signatures by early showering photons. Then, strips and charged hadrons are combined to reconstruct the following combinations: single hadron, hadron plus a strip, hadron plus two strips and three hadrons. To reduce the contamination from quark and gluon jets, the $\tau_{\text{ch}}$ candidate isolation is calculated in a cone of $\Delta R = 0.5$ around the reconstructed $\tau$-momentum direction. It is required that there be no charged hadrons with $p_T > 1.0$ GeV/$c$ and no photons with $E_T > 1.5$ GeV in the isolation cone, other than the $\tau$ decay particles. Additional requirements are applied to discriminate genuine $\tau$ leptons from prompt electrons and muons. The $\tau$
charge is taken as the sum of the charges of the charged hadrons (prongs) in the signal cone; its uncertainty is less than 1% and it is estimated from same sign \(Z \rightarrow \tau \tau \rightarrow \mu \tau_b\) events [27]. The \(\tau\) reconstruction efficiency of this algorithm is estimated to be approximately 37% (i.e. “medium” working point in Ref. [26]) for \(p_T^{m} > 20 \text{ GeV}/c\), and it is measured in a sample enriched in \(Z \rightarrow \tau \tau \rightarrow \mu \tau_b\) events with a “tag-and-probe” technique [28]. The medium working point corresponds to a probability of approximately 0.5% for generic hadronic jets to be misidentified as \(\tau_b\).

For the \(e\tau_b\) final state, events are triggered by the combined electron plus two jets plus \(H_T^{\text{miss}}\) trigger (\(e + \text{dijet} + H_T^{\text{miss}}\)), where \(H_T^{\text{miss}}\) is the absolute value of the vectorial sum of all jet momenta in the plane transverse to the beams. The thresholds for the electron and for \(H_T^{\text{miss}}\) are respectively \(p_T > 17–27 \text{ GeV}/c\) and \(H_T^{\text{miss}} > 15–20 \text{ GeV}\) depending on the data-taking period, and the \(p_T\) thresholds for the two jets are 30 GeV/c and 25 GeV/c. The trigger efficiency is estimated from a suite of triggers with lower thresholds assuming the factorization \(\epsilon_{\text{trig}} = \epsilon_e \times \epsilon_{\text{jets}} \times \epsilon_{\text{MHT}}\), where \(\epsilon_e\) is the electron efficiency, \(\epsilon_{\text{jets}}\) is the efficiency for selecting two jets, and \(\epsilon_{\text{MHT}}\) is the efficiency for \(H_T^{\text{miss}}\). The data-to-simulation scale factor for the electron trigger efficiency is 0.99 ± 0.01. The efficiencies \(\epsilon_{\text{MHT}} = 1.00^{+0.00}_{-0.01}\) and \(\epsilon_{\text{jets}}\), which is parameterized as a function of jet \(p_T\), are estimated from data. In the \(\mu\tau_b\) final state, data are collected with a trigger requiring at least one isolated muon with threshold of \(p_T > 17\) (24) GeV/c, for the earlier (later) part of the data sample; the data-to-simulation scale factor for the trigger efficiency is 0.99 ± 0.01.

Events are selected by requiring one isolated electron (muon) with transverse momentum \(p_T > 35\) (30) GeV/c and \(|\eta| < 2.5\) (2.1), at least two jets with \(p_T > 35\) (30) GeV/c and \(|\eta| < 2.4\), missing transverse energy \(E_T^{\text{miss}} > 45\) (40) GeV and one hadronically decaying \(\tau\) lepton (\(\tau\) jet) with \(p_T > 20 \text{ GeV}/c\) and \(|\eta| < 2.4\). Electrons or muons are required to be separated from any jet in the \((\eta, \phi)\) plane by a distance \(\Delta R > 0.3\). Events with any additional loosely isolated \((I_{\text{rel}} < 0.2)\) electron (muon) of \(p_T > 15\) (10) GeV/c are rejected.

The \(\tau\) jet and the lepton are required to have electric charges of opposite sign (OS). At least one of the jets is required to be identified as originating from \(b\) quark hadronization (\(b\) tagged). The \(b\)-tagging algorithm used (“TCHEL” in Ref. [29]) is based on sorting tracks according to their impact parameter significance \((S_{\text{ip}})\); the \(S_{\text{ip}}\) value of the second track is used as the discriminator. The \(b\)-tagging efficiency of this algorithm is 76 ± 1%, measured in a sample of events enriched with jets from semileptonic \(b\)-hadron decays. The misidentification rate of light-flavor jets is obtained from inclusive jet studies and is measured to be 13 ± 3% for jets in the \(p_T\) range relevant to this analysis. After the final event selection, a fraction of approximately 12% of the generated \(\tau\) tau dilepton events within the geometric and kinematic fiducial region are selected.

The \(b\)-tagged jet multiplicity for the \(e\tau_b\) and \(\mu\tau_b\) final states is shown in Fig. 1 for the events in the preselected sample, i.e. one isolated electron (muon), missing transverse energy above 45 (40) GeV, and at least three jets, two jets with \(p_T > 35\) (30) GeV/c and one jet with \(p_T > 20 \text{ GeV}/c\). The observed numbers of events are consistent with the expected numbers of signal and background events obtained from the simulation. The distributions of the \(E_T^{\text{miss}}\) and of the transverse momentum of the \(\tau\) lepton

after the final event selection are shown in Fig. 2 and in Fig. 3, respectively, for both the $e\tau_h$ and $\mu\tau_h$ final states. The distributions show good agreement between the observed numbers of events and the expected numbers of signal and background events obtained from the simulation. The $E_T^{\text{miss}}$ distribution for the $e\tau_h$ final state has a deficit of events in the first bin due to the higher $E_T^{\text{miss}}$ threshold, when compared to the $e\tau_h$ final state.

The top quark mass is reconstructed with the KINb [30] algorithm (Fig. 4), treating the additional neutrino in the $\tau$ decay as a contribution to the $E_T^{\text{miss}}$. Numerical solutions for the kinematic reconstruction of $t\bar{t}$ decays with two charged leptons in the final state are found for each event. The jet transverse momentum, the $E_T^{\text{miss}}$ direction, and the longitudinal momentum of the $t\bar{t}$ system are varied independently within their measured resolutions to scan the kinematic phase space compatible with the $t\bar{t}$ system. Solutions with the lowest invariant mass of the $t\bar{t}$ system are accepted if the difference between the two top quark masses is less than $3 \text{ GeV}/c^2$. The reconstructed top quark mass in Fig. 4 shows that the kinematic properties of the

selected events are statistically compatible with predictions based on a top quark mass of 172.5 GeV/c$^2$, indicating the consistency of the selected sample in data with the sum of top quark pair production plus the background.

V. BACKGROUND ESTIMATE

The background comes from two categories of events, the “misreconstructed $\tau$” background ($N_{\text{misid}}$) which is estimated from data, and the “other” background ($N_{\text{other}}$) which is estimated from simulation.

The main background (misreconstructed $\tau$) comes from events with one lepton (electron or muon), $E_T^{\text{miss}}$ requirement and three or more jets, where one jet is misidentified as a $\tau$ jet. The dominant contribution to this background is from events where one $W$ boson is produced in association with jets, and from $t\bar{t} \rightarrow W^+ b W^- b \rightarrow \ell v b q\bar{q}' b$ events. In order to estimate this background from data, the probability $w_{(jet \rightarrow \tau_b)}$ that a jet is misidentified as a $\tau$ jet as a function of the jet $p_T$, $\eta$, and jet width ($R_{\text{jet}}$) is determined, then applied to every jet in the preselected sample with one $b$-tagged jet. The quantity $R_{\text{jet}}$ is defined as $\sqrt{\sigma_{\eta \eta}^2 + \sigma_{\phi \phi}^2}$, where $\sigma_{\eta \eta}$ ($\sigma_{\phi \phi}$) expresses the extent in $\eta$ ($\phi$) of the jet cluster. Thus the expected number of background is obtained as:

$$N_{\text{misid}} = \sum_i^n \sum_j^m w_j^i (\text{jet} \rightarrow \tau) - N_{\text{other}}, \quad (1)$$

where $j$ is the jet index of the event $i$. The quantity $N_{\text{other}}$ is the small ($\approx 18\%$) contamination of other contributions to the misidentified $\tau$ background, which is estimated from simulation. This is mostly due to the presence of genuine $\tau$ jets in the $W^+ \pm 3$ jet sample. In order to estimate this contribution, the same procedure described above is applied to simulated events of $Z/\gamma^* \rightarrow \tau\tau$, single top quark production, diboson production, and the part of the SM $t\bar{t}$ background not included in the misidentified $\tau$ background estimate.

In order to estimate the misidentification probability, the hadronic multijet events are selected from a sample triggered by at least one jet with $p_T > 30$ GeV/c, by requiring events to have at least two jets with $p_T > 20$ GeV/c and $|\eta| < 2.4$. The triggering jet is removed from the misidentification rate calculation in order to avoid a trigger bias. The $W^+ \pm 1$ jet events are selected by requiring only one isolated muon with $p_T > 20$ GeV/c and $|\eta| < 2.1$, and at least one jet with $p_T > 20$ GeV/c and $|\eta| < 2.4$. The probability $w_{(jet \rightarrow \tau_b)}$ is evaluated from all jets in a sample enriched in QCD multijet events ($w_{\text{QCD}}$), and all jets in another sample enriched in $W^+ \pm 1$ jet events ($w_{W^+\text{jets}}$). The probability that a jet is misidentified as a $\tau$ jet as a function of jet $p_T$, $\eta$ and $R_{\text{jet}}$ is compared between simulated events ($Z2$ tune [11]) and data, and a good agreement is found [26].

Jets in QCD multijet events are mainly gluon jets ($\approx 75\%$ obtained from simulation), while the jets in $W^+ \pm 1$ jet events are predominantly quark jets ($\approx 64\%$ obtained from simulation), where $w_{\text{QCD}} < w_{W^+\text{jets}}$. Since the quark and gluon jet composition in $\ell + E_T^{\text{miss}} + \geq 3$ jet events lies between two categories of events, QCD multijet and $W^+ \pm 1$ jet events, the $N_{\text{misid}}$ value is under- (over-) estimated by applying the $w_{\text{QCD}} (w_{W^+\text{jets}})$ probability. Thus, the $N_{\text{misid}}$ and its systematic uncertainty are estimated as in the following:

$$N_{\text{misid}} = \sum_i^n \sum_j^m w_{W^+\text{jets},i}^j + \sum_i^n \sum_j^m w_{\text{QCD},i}^j, \quad (2)$$
\[
\Delta N_{\text{misid}} = \frac{\sum_i^N \sum_j^j w^j_{W+jets,i} - \sum_i^N \sum_j^j w^j_{QCD,i}}{2}.
\] (3)

The contribution of \(N_{\text{other}}\) described earlier is subtracted from Eq. (2). Finally, the efficiency \(e_{\text{OS}}\) of the OS requirement obtained from simulated events is applied to obtain the misidentified \(\tau\) background \(N_{\text{misid}} = e_{\text{OS}} \times N_{\text{misid}}\). The estimated efficiencies for the \(e\tau_h\) and \(\mu\tau_h\) final states are \(e_{\text{OS}} = 0.72 \pm 0.09\) (stat) \(\pm 0.02\) (syst) and \(e_{\text{OS}} = 0.69 \pm 0.07\) (stat) \(\pm 0.03\) (syst), respectively, where the statistical uncertainty comes from the limited number of simulated events, and the systematic uncertainty is taken as half of the difference of the efficiency estimated from \(W + \) jets and lepton + jet \(t\bar{t}\) simulated events.

Other backgrounds in this analysis are \(Z/\gamma^* \to \tau\tau\), single top quark production, diboson production, and the part of the SM \(t\bar{t}\) background not included in the misidentified \(\tau\) background, and are estimated from simulation. Events from \(Z \to ee\), \(\mu\mu\) are also taken into account because they contain misidentified \(\tau\) jets, where the misidentified \(\tau\) lepton can originate from an electron or muon misidentified as a \(\tau\) jet. The statistical uncertainties are due to the limited number of simulated events.

VI. SYSTEMATIC UNCERTAINTIES

Different sources of systematic uncertainties on the measurement of the cross section due to signal selection efficiencies and backgrounds are considered, as shown in Table I. The main sources of systematic uncertainties are due to \(\tau\) identification, \(b\)-tagging and mistagging efficiencies, jet energy scale (JES), jet energy resolution (JER), \(E_T^{\text{miss}}\) scale, and to the estimate of the misreconstructed \(\tau\) background (from data). The systematic uncertainties for the determination of the misidentified \(\tau\) background are discussed in detail in Sec. V.

The uncertainty on the \(\tau\) jet identification includes contributions from \(\tau\) identification efficiency and \(\ell \to \tau_h\) (\(\ell = e, \mu\)) misidentification. The uncertainty on \(\tau\) identification efficiency is estimated to be 6\% (from an updated measurement with respect to [26]), and it includes the uncertainty on charge determination which is estimated to be smaller than 1\%. The uncertainty on the \(\ell \to \tau_h\) misidentification rate is estimated as the difference of \(\tau\) misidentification rate measured in data and in simulated events, and is taken to be 15\% [26]. These uncertainties are applied to the simulated \(Z \to ee\), \(\mu\mu\), and \(t\bar{t}\) dilepton backgrounds.

The uncertainties related to \(b\)-tagging and mistagging efficiencies are estimated from a variety of control samples enriched in \(b\) quarks, and the data-to-simulation scale factors amount to \(0.95 \pm 0.06\) and \(1.11 \pm 0.11\), respectively [29].

The uncertainties on JES, JER, and \(E_T^{\text{miss}}\) scale are estimated according to the prescription described in Ref. [32]. These uncertainties also take into account the uncertainty due to the JES dependence on the parton flavor. The uncertainty on JES is evaluated as a function of jet \(p_T\) and jet \(\eta\). The JES and JER uncertainties are propagated in order to estimate the uncertainty of the \(E_T^{\text{miss}}\) scale. An additional 10\% uncertainty on the contribution to \(E_T^{\text{miss}}\) coming from the energy of particles that are not clustered into jets is also taken into account.

The theoretical uncertainty on the signal acceptance is estimated to be 4\% [30]. It accounts for variations in the renormalization and factorization scales (2\%), \(\tau\) lepton and hadron decay modelling (2\%), top quark mass (1.6\%), leptonic branching fractions of the \(W\) boson (1.7\%), and

**VII. CROSS SECTION MEASUREMENT**

The number of events expected from the backgrounds, the number of signal events from $t\bar{t}$, and the number of observed events after all selection cuts are summarized in Table II. The statistical and systematic uncertainties are also shown.

The $t\bar{t}$ production cross section measured from tau dilepton events is:

$$
\sigma_{t\bar{t}} = \frac{N - B}{L \cdot A_{tot}},
$$

(4)

where $N$ is the number of observed candidate events, $B$ is the estimate of the background, $L$ is the integrated luminosity. The total acceptance $A_{tot}$ is the product of all branching fractions, geometrical and kinematical acceptance, efficiencies for trigger, lepton identification and the overall reconstruction efficiency, and it is evaluated with respect to the inclusive $t\bar{t}$ sample. After the OS requirement:

$$
A_{tot}(e\tau_b) = [0.0304 \pm 0.0009(\text{stat}) \pm 0.0031(\text{syst})]\%;
$$

(5)

$$
A_{tot}(\mu\tau_b) = [0.0443 \pm 0.0011(\text{stat}) \pm 0.0047(\text{syst})]\%.
$$

(6)

The statistical uncertainties are due to the limited number of simulated events and the systematic uncertainties are estimated by varying all sources of systematics in Table I affecting the signal (i.e., all uncertainties except for the luminosity and for the background). All systematic and statistical uncertainties in Table II are propagated from Eq. (4) to the final cross section measurement. The measured $t\bar{t}$ cross section is:

$$
\sigma_{t\bar{t}}(e\tau_b) = 136 \pm 23(\text{stat}) \pm 23(\text{syst}) \pm 3(\text{lumi}) \text{ pb};
$$

(7)

$$
\sigma_{t\bar{t}}(\mu\tau_b) = 147 \pm 18(\text{stat}) \pm 22(\text{syst}) \pm 3(\text{lumi}) \text{ pb}.
$$

(8)

The Best Linear Unbiased Estimation method [31] is used to combine the cross section measurements in the $e\tau_b$ and $\mu\tau_b$ channels with the associated uncertainties and correlation factors. Systematic uncertainties common to the two channels are assumed to be 100% correlated. The combined result is

$$
\sigma_{t\bar{t}} = 143 \pm 14(\text{stat}) \pm 22(\text{syst}) \pm 3(\text{lumi}) \text{ pb},
$$

(9)

in agreement with the measured values in the dilepton [30] and lepton + jet [34,35] final states, and with the SM expectations in the approximate NNLO calculation of $163^{+13}_{-9}(\text{scale}) \pm 9(\text{PDF}) \text{ pb} [36].

**VIII. SUMMARY**

We present the first measurement of the $t\bar{t}$ production cross section in the tau dilepton channel $t\bar{t} \rightarrow (\ell \nu_\ell)(\tau_b \nu_\tau)bb$, $(\ell = e, \mu)$ with data samples corresponding to an integrated luminosity of 2.0–2.2 fb$^{-1}$ collected in proton-proton collisions at $\sqrt{s} = 7$ TeV. Events are selected by requiring the presence of one electron or muon, two or more jets (at least one jet is $b$ tagged), missing transverse energy, and one hadronically decaying $\tau$ lepton. The largest background contributions come from events where one $W$ boson is produced in association with jets, and from $t\bar{t} \rightarrow W^+bW^-\bar{b} \rightarrow \ell\nu_b(q\bar{q}'\bar{b})$ events, where one jet is misidentified as the $\tau$, and from $Z \rightarrow \tau\tau$ events. The measured cross section is $\sigma_{t\bar{t}} = 143 \pm 14(\text{stat}) \pm 22(\text{syst}) \pm 3(\text{lumi}) \text{ pb}$, in agreement with SM expectations.
ACKNOWLEDGMENTS

We wish to congratulate our colleagues in the CERN accelerator departments for the excellent performance of the LHC machine. We thank the technical and administrative staff at CERN and other CMS institutes, and acknowledge support from: FMSR (Austria); FNRS and FWO (Belgium); CNaSPq, CAPES, FAPEB, and FAPESP (Brazil); MES (Bulgaria); CERN; CAS, MoST, and NSFC (China); COLCIENCIAS (Colombia); MSES (Croatia); RPF (Cyprus); MoER, SF0690030s09 and NSFC (China); COLCIENCIAS (Colombia); MSES (Croatia); RPF (Cyprus); MoER, SF0690030s09 and NSFC (China); COLCIENCIAS (Colombia); MSES (Croatia); RPF (Cyprus); MoER, SF0690030s09 and NSFC (China); COLCIENCIAS (Colombia); MSES (Croatia); RPF (Cyprus); MoER, SF0690030s09 and NSFC (China); COLCIENCIAS (Colombia); MSES (Croatia); RPF (Cyprus); MoER, SF0690030s09 and NSFC (China). Individuals have received support from the Marie-Curie programme and the European Research Council (European Union); the Leventis Foundation; the A.P. Sloan Foundation; the Alexander von Humboldt Foundation; the Belgian Federal Science Policy Office; the Fonds pour la Formation à la Recherche dans l'Industrie et dans l'Agriculture (FRIA-Belgium); the Agentschap voor Innovatie door Wetenschap en Technologie (IWT-Belgium); the Council of Science and Industrial Research, India; and the HOMING PLUS programme of Foundation for Polish Science, cofinanced from European Union, Regional Development Fund.

PHYSICAL REVIEW D 85, 112007 (2012)
University of Virginia, Charlottesville, USA
Wayne State University, Detroit, USA
University of Wisconsin, Madison, USA

\textsuperscript{a}Deceased.
\textsuperscript{b}Also at CERN, European Organization for Nuclear Research, Geneva, Switzerland.
\textsuperscript{c}Also at National Institute of Chemical Physics and Biophysics, Tallinn, Estonia.
\textsuperscript{d}Also at Universidade Federal do ABC, Santo Andre, Brazil.
\textsuperscript{e}Also at California Institute of Technology, Pasadena, USA.
\textsuperscript{f}Also at Laboratoire Leprince-Ringuet, Ecole Polytechnique, IN2P3-CNRS, Palaiseau, France.
\textsuperscript{g}Also at Suez Canal University, Suez, Egypt.
\textsuperscript{h}Also at Cairo University, Cairo, Egypt.
\textsuperscript{i}Also at British University, Cairo, Egypt.
\textsuperscript{j}Also at Fayoum University, El-Fayoum, Egypt.
\textsuperscript{k}Also at Soltan Institute for Nuclear Studies, Warsaw, Poland.
\textsuperscript{l}Also at Université de Haute-Alsace, Mulhouse, France.
\textsuperscript{m}Also at Moscow State University, Moscow, Russia.
\textsuperscript{n}Also at Brandenburg University of Technology, Cottbus, Germany.
\textsuperscript{o}Also at Institute of Nuclear Research ATOMKI, Debrecen, Hungary.
\textsuperscript{p}Also at Eötvös Loránd University, Budapest, Hungary.
\textsuperscript{q}Also at Tata Institute of Fundamental Research - HECR, Mumbai, India.
\textsuperscript{r}Also at University of Visva-Bharati, Santiniketan, India.
\textsuperscript{s}Also at Sharif University of Technology, Tehran, Iran.
\textsuperscript{t}Also at Isfahan University of Technology, Isfahan, Iran.
\textsuperscript{u}Also at Shiraz University, Shiraz, Iran.
\textsuperscript{v}Also at Plasma Physics Research Center, Science and Research Branch, Islamic Azad University, Tehran, Iran.
\textsuperscript{w}Also at Facoltà Ingegneria Università di Roma, Roma, Italy.
\textsuperscript{x}Also at Università della Basilicata, Potenza, Italy.
\textsuperscript{y}Also at Università degli Studi Guglielmo Marconi, Roma, Italy.
\textsuperscript{z}Also at Università degli studi di Siena, Siena, Italy.
\textsuperscript{aa}Also at Faculty of Physics of University of Belgrade, Belgrade, Serbia.
\textsuperscript{ab}Also at University of Florida, Gainesville, USA.
\textsuperscript{ac}Also at University of California, Los Angeles, Los Angeles, USA.
\textsuperscript{ad}Also at University of Sydney, Sydney, Australia.
\textsuperscript{ae}Also at INFN Sezione di Roma, Università di Roma “La Sapienza”, Roma, Italy.
\textsuperscript{af}Also at University of Athens, Athens, Greece.
\textsuperscript{ag}Also at Rutherford Appleton Laboratory, Didcot, United Kingdom.
\textsuperscript{ah}Also at The University of Kansas, Lawrence, USA.
\textsuperscript{ai}Also at Paul Scherrer Institut, Villigen, Switzerland.
\textsuperscript{aj}Also at Institute for Theoretical and Experimental Physics, Moscow, Russia.
\textsuperscript{ak}Also at Gaziosmanpasha University, Tokat, Turkey.
\textsuperscript{al}Also at Adiyaman University, Adiyaman, Turkey.
\textsuperscript{am}Also at The University of Iowa, Iowa City, USA.
\textsuperscript{an}Also at Mersin University, Mersin, Turkey.
\textsuperscript{ao}Also at Kafkas University, Kars, Turkey.
\textsuperscript{ap}Also at Suleyman Demirel University, Isparta, Turkey.
\textsuperscript{aq}Also at Ege University, Izmir, Turkey.
\textsuperscript{ar}Also at School of Physics and Astronomy, University of Southampton, Southampton, United Kingdom.
\textsuperscript{as}Also at INFN Sezione di Perugia, Università di Perugia, Perugia, Italy.
\textsuperscript{au}Also at University of Sydney, Sydney, Australia.
\textsuperscript{av}Also at Utah Valley University, Orem, USA.
\textsuperscript{aw}Also at Institute for Nuclear Research, Moscow, Russia.
\textsuperscript{ax}Also at University of Belgrade, Faculty of Physics and Vinca Institute of Nuclear Sciences, Belgrade, Serbia.
\textsuperscript{ay}Also at Argonne National Laboratory, Argonne, USA.
\textsuperscript{az}Also at Erzincan University, Erzincan, Turkey.
\textsuperscript{b}Also at Kyungpook National University, Daegu, Korea.
