The Feasibility Conditions for Interference Alignment in MIMO Networks

Liangzhong Ruan, Student Member, IEEE, Vincent K.N. Lau, Fellow, IEEE, and Moe Z. Win, Fellow, IEEE

Abstract—Interference alignment (IA) has attracted great attention in the last few years for its breakthrough performance in interference networks. However, despite the numerous works dedicated to IA, the feasibility conditions of IA remains unclear for most network topologies. The IA feasibility analysis is challenging as the IA constraints are sets of high-degree polynomials, for which no systematic tool to analyze the solvability conditions exists. In this work, by developing a new mathematical framework that maps the solvability of sets of polynomial equations to the linear independence of their first-order terms, we propose a sufficient condition that applies to MIMO interference networks with general configurations. We have further proved that this sufficient condition matches with the necessary conditions under a wide range of configurations. These results further consolidate the theoretical basis of IA.

I. INTRODUCTION

Interference has been a fundamental performance bottleneck in wireless communication. Conventional schemes either treat interference as noise or use channel orthogonalization to avoid interference. However, these schemes are non-capacity achieving in general. Interference alignment (IA), first proposed in [1], significantly improves the performance of interference networks by aligning the aggregated interference from multiple sources into a lower dimensional subspace. For instance, in a system with $K$ transmitter-receiver (Tx-Rx) pairs and $N$ antennas at each node, the IA achieves a total throughput which scales as $O\left(\frac{K}{N} \log(\text{SNR})\right)$ [2]. This scaling law is optimal and well dominates that of conventional orthogonalization schemes, i.e. $O\left(N \log(\text{SNR})\right)$. The IA solution in [2] is also applied to other topologies such as the MIMO-X channels [3] and MIMO relay channels [4] and achieves the optimal throughput scaling law. As such, there is a surge in the research interests of IA.

To achieve the optimal scaling law of throughput, the IA solution in [2] requires $O((KN)^{2K^2N^2})$ dimensions of signal space, which is realized by time or frequency domain symbol extension. Such symbol extension approach is difficult to implement in practice due to the huge dimensions of the signal space involved. To overcome this problem, IA designs with signal space dimension limited by the number of antennas, are proposed in [5]–[9] for practical MIMO systems. In the IA designs proposed in [5]–[7], closed-form solutions are obtained for few specific and simple configurations. For instance, in [5], all Rx have 2 antennas. In [6], all nodes have $(K + 1)$ antennas. And in [7], there are only 2 Rxs in the network. Moreover, in all the works mentioned above, each Tx only has one independent data stream. Iterative IA solutions based on alternating optimization are proposed for MIMO interference networks with general configurations in [8], [9]. However, these approaches may not converge to the global optimal solution.

When the signal space dimension is limited, the IA is not always feasible. Therefore, the characterization of the feasibility conditions under limited signal space dimension is the primary issue to address. In general, the feasibility of the IA problem is associated with the solvability of a set of polynomial equations, which is the focus of algebraic geometry [10], [11]. There are very few works that studied the feasibility condition of IA problems using algebraic geometry [12]–[15]. In [12], the authors studied the feasibility condition of IA problem in single stream MIMO interference networks using Bernstein’s Theorem in algebraic geometry [11], Thm. 5.4, Ch. 7]. This work has been extended to the multiple stream case by two parallel works [13], and [14,15], respectively. The first approach in [13] established some necessary conditions for the IA feasibility condition for general network topology by analyzing the dimension of the algebraic varieties [10]. The authors further showed that these conditions are also sufficient when the number of antennas and data streams at every node are identical. The second approach in [14], [15] established a similar necessary conditions for the IA feasibility problem based on algebraic independence between the IA constraints. The authors further proved that these conditions are also sufficient when the number of data stream at every node is the same and the number of antennas at every node is divisible by the number of data streams. In summary, the aforementioned works have proposed some necessary conditions for MIMO interference networks with general configuration, but the proposed sufficient conditions are limited to specific configurations.

In this paper, we develop new tools in algebraic geometry which allows us to address the IA feasibility issue in the general configuration. The newly developed tool maps the solvability of a set of general polynomial equations to the linear independence of their first order terms. Based on this new tool, we can extend our understanding on the IA feasibility conditions in the following aspects:
A. Further tighten the IA feasibility conditions from the necessary side;
B. Propose and prove a sufficient condition of IA feasibility which applies to MIMO interference networks with general configurations;
C. Prove that scaling the number of antennas and data streams of a network simultaneously preserves IA feasibility;
D. Determine the necessary and sufficient conditions of IA feasibility in a wider range of network configurations comparing with the results given in [13]–[15].

Organization: Section II presents the system model and define the IA feasibility problem. Section III-A pairs the analytical results of this paper to their contributions. Section II-B provides the proofs of the results based on a new mathematical framework. Section IV concludes the discussion.

Notations: $a$, $a$, $A$, and $A$ represent scalar, vector, matrix, set/space, respectively. $\mathbb{N}$, $\mathbb{Z}$ and $\mathbb{C}$ denote the set of natural numbers, integers and complex numbers, respectively. The operators $\langle \cdot \rangle^T$, $\langle \cdot \rangle^H$, $\det(\cdot)$, $\text{rank}(\cdot)$, and $\mathcal{N}(\cdot)$ denote transpose, Hermitian transpose, determinant, rank, and null space of a matrix. And the operators $\langle \cdot \rangle$, $\mathcal{V}(\cdot)$ denote the ideal, and the vanishing set $\{16\}$ of a set of polynomials. For a field $K$, $K[x_1, ..., x_j]$ represents the field of rational functions in variables $x_1, ..., x_j$ with coefficients drawn from $K$. size($\cdot$) represents the size of a vector and $|\cdot|$ represents the cardinality of a set. $I(\cdot)$ is the indicator function. dim($\cdot$) denotes the dimension of a space. span($A$) and span($\{a\}$) denote the linear space spanned by the column vectors of $A$ and the vectors in set $\{a\}$, respectively. gcd($n, m$) denotes the greatest common divisor of $n$ and $m$, and $n|m$ denotes that $n$ divides $m$, and mod($n, m$) denotes $n$ modulo $m$, $n, m \in \mathbb{Z}$. diag$^n(A, ..., X)$ represents a block diagonal matrix with submatrices $A, ..., X$ on its $n$-th diagonal. For instance, diag$^{-1}([2, 1], [1, 2]) = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 2 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix}$. diag$\{A, ..., X\} = \text{diag}(A, ..., X)$, and diag$[n](A) = \text{diag}(A, ..., A, ..., A)$. The symbol “$\cong$” denotes the isomorphism relation $[17]$.

II. SYSTEM MODEL AND PROBLEM FORMULATION

Consider a MIMO interference network consisting of $K$ Tx-Rx pairs, with $T$ $T$ sending $d_k$ independent data streams to $R$ $R$ antennas. $T$ is equipped with $M_k$ antennas and $R$ has $N_k$ antennas. The received signal $y_k \in \mathcal{C}^{d_k}$ at $R$ is given by:

$$ y_k = U_k^H \left( H_{kk} V_k x_k + \sum_{j=1,j \neq k}^{K} H_{kj} V_j x_j + z \right) $$

where $H_{kk} \in \mathcal{C}^{N_k \times M_k}$ is the channel state matrix from $T$ to $R$, whose entries are independent random variables drawn from continuous distributions. $x_k \in \mathcal{C}^{d_k}$ is the encoded information symbol for $R$, $U_k \in \mathcal{C}^{d_k \times d_k'}$ is the precoder matrix at $T$. $z \in \mathcal{C}^{N_k \times 1}$ is the white Gaussian noise with zero mean and unit variance.

Following the previous works on IA for $K$-pairs MIMO interference networks [12]–[15], [18], in this work, we focus on the feasibility issue of the following problem:

**Problem 1 (IA on MIMO Interference Networks):**

For a MIMO interference network with configuration $\chi = \{(M_1, N_1, d_1), (M_2, N_2, d_2), ..., (M_K, N_K, d_K)\}$, design transceivers $\{U_k \in \mathcal{C}^{N_k \times d_k}, V_j \in \mathcal{C}^{M_j \times d_j}\}$, $k, j \in \{1, ..., K\}$ that satisfy the following constraints:

$$ \text{rank}(U_k^H H_{kk} V_k) = d_k, \quad \forall k, \quad (2) $$

$$ U_k^H H_{kk} V_j = 0, \quad \forall k \neq j. \quad (3) $$

III. FEASIBILITY CONDITIONS

In this section, we will first list the main results and pair them with the contributions. Then we prove these results in the second subsection. Readers can refer to [19] for a summary of the main theoretical approaches prior to this work, and a brief introduction to the concept of algebraic independence.

A. Main Results

1) Theorems Applicable to General Configurations: The following two theorems summarize the main result on the necessary side and the sufficient side, respectively.

**Theorem 3.1 (Necessary Conditions of IA Feasibility):** If Problem 1 has solution, then the network configuration $\chi$ must satisfy the following inequalities:

$$ \min\{M_j, N_j\} \geq d_j, \quad \forall j \in \{1, ..., K\} \quad (4) $$

$$ \max\{ \sum_{j \in \mathcal{J}} M_j, \sum_{j \in \mathcal{J}} N_j \} \geq \sum_{j \in \mathcal{J}} d_j, \quad \forall \mathcal{J} \subseteq \mathcal{J}_{sub} \quad (5) $$

$$ \sum_{j \in \mathcal{J}} (M_j - d_j) + \sum_{j \in \mathcal{J}} (N_j - d_k) \geq \sum_{j \in \mathcal{J}} d_j d_k, \quad \forall \mathcal{J} \subseteq \mathcal{J}_{sub} \quad (6) $$

where $\mathcal{J}_{sub} \subseteq \mathcal{J}$, where $\mathcal{J} = \{(k, j) : k, j \in \{1, ..., K\}, k \neq j\}$, and $(k, j)$ or $(k, \cdot)$ or $(\cdot, j)$ or $(\cdot, \cdot)$ denotes that there exists $k$ or $j$ in $\{1, ..., K\}$ such that $(k, j) \in \mathcal{J}_{sub}$. $\square$

**Remark 3.1 (Tighter Necessary Conditions):** (5) is the newly proposed necessary condition. If the cardinality of set $\mathcal{J}_{sub}$ is restricted to be 1, we have that (5) is reduced to

$$ \max\{M_j, N_j\} \geq d_k + d_j, \quad \forall j \neq k, \quad (7) $$

which is one of the necessary inequalities given in the prior works [13]–[15]. Note that the necessary conditions given in Thm. 3.1 are strictly tighter than those given in [13]–[15]. $\square$

**Theorem 3.2 (Sufficient Condition of IA Feasibility):** If the matrix described in Fig. I (denote this matrix as $H_{\text{all}}$) is full row rank, Problem 1 has solutions almost surely.

The submatrices $H_{kj}^U \in \mathcal{C}^{d_k d_j}$ are defined by:

$$ H_{kj}^U = \begin{bmatrix} h_{kj}(d_k+1,1) & h_{kj}(d_k+1,2) & \cdots & h_{kj}(N_k,1) \\ h_{kj}(d_k+1,2) & h_{kj}(d_k+2,2) & \cdots & h_{kj}(N_k,2) \\ \vdots & \vdots & \ddots & \vdots \\ h_{kj}(d_k+1,d_k) & h_{kj}(d_k+d_k,2) & \cdots & h_{kj}(N_k,d_k) \end{bmatrix} \quad (8) $$

The submatrices $H_{kj}^V \in \mathcal{C}^{d_j}$ are defined by:

$$ H_{kj}^V = \begin{bmatrix} h_{kj}(d_k+1,1) & h_{kj}(d_k+1,1) & \cdots & h_{kj}(d_k+1,1) \\ h_{kj}(d_k+1,2) & h_{kj}(d_k+1,2) & \cdots & h_{kj}(d_k+1,2) \\ \vdots & \vdots & \ddots & \vdots \\ h_{kj}(d_k+d_k,2) & h_{kj}(d_k+d_k,2) & \cdots & h_{kj}(d_k+d_k,2) \end{bmatrix} \quad (9) $$
Fig. 1. The matrix scattered by the coefficient vectors of the linear terms in the polynomial form of IA constraints, i.e.

$$\begin{bmatrix} X_1 & X_2 & \cdots & X_K \end{bmatrix}$$

where $X_i$ are the polynomial coefficients.

Remark 3.2 (Interpretation of the Sufficient Condition): If $H_{ij}$, $i \neq j$, is zero, then the $i$-th row and $j$-th column of $\mathbf{H}$ are linearly independent. Hence, $\mathbf{H}$ is full rank in terms of polynomials in the IA constraint (3).

The row vectors of $\mathbf{H}$ are the coefficients of the linear terms in the polynomial form of IA constraints. We only need to randomly generate a specific configuration. Then, we can try to construct some specific channel state that makes $\mathbf{H}$ feasible. Similarly, to prove that a certain state and check if $\mathbf{H}$ is full rank. The following analysis indicates that the conditions in the row independence of these coefficient vectors are sufficient for the $i$-th row and $j$-th column of $\mathbf{H}$ to be linearly independent. Hence, $\mathbf{H}$ is full rank in terms of polynomials in the IA constraint (3).

Remark 3.3 (Interpretation of the Sufficient Condition): If $H_{ij}$, $i \neq j$, is zero, then the $i$-th row and $j$-th column of $\mathbf{H}$ are linearly independent. Hence, $\mathbf{H}$ is full rank in terms of polynomials in the IA constraint (3).

The row vectors of $\mathbf{H}$ are the coefficients of the linear terms in the polynomial form of IA constraints. We only need to randomly generate a specific configuration. Then, we can try to construct some specific channel state that makes $\mathbf{H}$ feasible. Similarly, to prove that a certain state and check if $\mathbf{H}$ is full rank. The following analysis indicates that the conditions in the row independence of these coefficient vectors are sufficient for the $i$-th row and $j$-th column of $\mathbf{H}$ to be linearly independent. Hence, $\mathbf{H}$ is full rank in terms of polynomials in the IA constraint (3).

Remark 3.5 (Backward Compatible to Tau): If the following conditions in the position of the submatrices

$$\begin{bmatrix} \mathbf{X}_1 & \mathbf{X}_2 & \cdots & \mathbf{X}_K \end{bmatrix}$$

where $\mathbf{X}_i$ are the positions of the submatrices. If $\mathbf{X}_i$, $i \neq j$, is zero, then the $i$-th row and $j$-th column of $\mathbf{H}$ are linearly independent. Hence, $\mathbf{H}$ is full rank in terms of polynomials in the IA constraint (3).

The row vectors of $\mathbf{H}$ are the coefficients of the linear terms in the polynomial form of IA constraints. We only need to randomly generate a specific configuration. Then, we can try to construct some specific channel state that makes $\mathbf{H}$ feasible. Similarly, to prove that a certain state and check if $\mathbf{H}$ is full rank. The following analysis indicates that the conditions in the row independence of these coefficient vectors are sufficient for the $i$-th row and $j$-th column of $\mathbf{H}$ to be linearly independent. Hence, $\mathbf{H}$ is full rank in terms of polynomials in the IA constraint (3).

Remark 3.6 (Backward Compatible to Tau): If the following conditions in the position of the submatrices

$$\begin{bmatrix} \mathbf{X}_1 & \mathbf{X}_2 & \cdots & \mathbf{X}_K \end{bmatrix}$$

where $\mathbf{X}_i$ are the positions of the submatrices. If $\mathbf{X}_i$, $i \neq j$, is zero, then the $i$-th row and $j$-th column of $\mathbf{H}$ are linearly independent. Hence, $\mathbf{H}$ is full rank in terms of polynomials in the IA constraint (3).

The row vectors of $\mathbf{H}$ are the coefficients of the linear terms in the polynomial form of IA constraints. We only need to randomly generate a specific configuration. Then, we can try to construct some specific channel state that makes $\mathbf{H}$ feasible. Similarly, to prove that a certain state and check if $\mathbf{H}$ is full rank. The following analysis indicates that the conditions in the row independence of these coefficient vectors are sufficient for the $i$-th row and $j$-th column of $\mathbf{H}$ to be linearly independent. Hence, $\mathbf{H}$ is full rank in terms of polynomials in the IA constraint (3).

Remark 3.7 (Backward Compatible to Tau): If the following conditions in the position of the submatrices

$$\begin{bmatrix} \mathbf{X}_1 & \mathbf{X}_2 & \cdots & \mathbf{X}_K \end{bmatrix}$$

where $\mathbf{X}_i$ are the positions of the submatrices. If $\mathbf{X}_i$, $i \neq j$, is zero, then the $i$-th row and $j$-th column of $\mathbf{H}$ are linearly independent. Hence, $\mathbf{H}$ is full rank in terms of polynomials in the IA constraint (3).

The row vectors of $\mathbf{H}$ are the coefficients of the linear terms in the polynomial form of IA constraints. We only need to randomly generate a specific configuration. Then, we can try to construct some specific channel state that makes $\mathbf{H}$ feasible. Similarly, to prove that a certain state and check if $\mathbf{H}$ is full rank. The following analysis indicates that the conditions in the row independence of these coefficient vectors are sufficient for the $i$-th row and $j$-th column of $\mathbf{H}$ to be linearly independent. Hence, $\mathbf{H}$ is full rank in terms of polynomials in the IA constraint (3).

Remark 3.8 (Backward Compatible to Tau): If the following conditions in the position of the submatrices

$$\begin{bmatrix} \mathbf{X}_1 & \mathbf{X}_2 & \cdots & \mathbf{X}_K \end{bmatrix}$$

where $\mathbf{X}_i$ are the positions of the submatrices. If $\mathbf{X}_i$, $i \neq j$, is zero, then the $i$-th row and $j$-th column of $\mathbf{H}$ are linearly independent. Hence, $\mathbf{H}$ is full rank in terms of polynomials in the IA constraint (3).

The row vectors of $\mathbf{H}$ are the coefficients of the linear terms in the polynomial form of IA constraints. We only need to randomly generate a specific configuration. Then, we can try to construct some specific channel state that makes $\mathbf{H}$ feasible. Similarly, to prove that a certain state and check if $\mathbf{H}$ is full rank. The following analysis indicates that the conditions in the row independence of these coefficient vectors are sufficient for the $i$-th row and $j$-th column of $\mathbf{H}$ to be linearly independent. Hence, $\mathbf{H}$ is full rank in terms of polynomials in the IA constraint (3).

Remark 3.9 (Backward Compatible to Tau): If the following conditions in the position of the submatrices

$$\begin{bmatrix} \mathbf{X}_1 & \mathbf{X}_2 & \cdots & \mathbf{X}_K \end{bmatrix}$$

where $\mathbf{X}_i$ are the positions of the submatrices. If $\mathbf{X}_i$, $i \neq j$, is zero, then the $i$-th row and $j$-th column of $\mathbf{H}$ are linearly independent. Hence, $\mathbf{H}$ is full rank in terms of polynomials in the IA constraint (3).

The row vectors of $\mathbf{H}$ are the coefficients of the linear terms in the polynomial form of IA constraints. We only need to randomly generate a specific configuration. Then, we can try to construct some specific channel state that makes $\mathbf{H}$ feasible. Similarly, to prove that a certain state and check if $\mathbf{H}$ is full rank. The following analysis indicates that the conditions in the row independence of these coefficient vectors are sufficient for the $i$-th row and $j$-th column of $\mathbf{H}$ to be linearly independent. Hence, $\mathbf{H}$ is full rank in terms of polynomials in the IA constraint (3).

Remark 3.10 (Backward Compatible to Tau): If the following conditions in the position of the submatrices

$$\begin{bmatrix} \mathbf{X}_1 & \mathbf{X}_2 & \cdots & \mathbf{X}_K \end{bmatrix}$$

where $\mathbf{X}_i$ are the positions of the submatrices. If $\mathbf{X}_i$, $i \neq j$, is zero, then the $i$-th row and $j$-th column of $\mathbf{H}$ are linearly independent. Hence, $\mathbf{H}$ is full rank in terms of polynomials in the IA constraint (3).

The row vectors of $\mathbf{H}$ are the coefficients of the linear terms in the polynomial form of IA constraints. We only need to randomly generate a specific configuration. Then, we can try to construct some specific channel state that makes $\mathbf{H}$ feasible. Similarly, to prove that a certain state and check if $\mathbf{H}$ is full rank. The following analysis indicates that the conditions in the row independence of these coefficient vectors are sufficient for the $i$-th row and $j$-th column of $\mathbf{H}$ to be linearly independent. Hence, $\mathbf{H}$ is full rank in terms of polynomials in the IA constraint (3).
\[ f_i = w_1 x_1 + w_2 x_2 \quad i \in \{1, 2\} \]
\[ f_i = w_1 x_1 + w_2 x_2 + g_i (x_1, x_2) \quad \text{where } g_i \text{ consist of terms with degree no less than 2.} \]
\[ f_i = c_i + w_1 x_1 + w_2 x_2 + g_i \quad \quad \{x_1, x_2 : f_i (x_1, x_2) = 0, \quad i \in \{1, 2\}\} \neq \emptyset \]

Fig. 2. Illustration of the new systematic tool that connects linear independece to the solvability of polynomial equation sets.

\[
\sum_{j: (-j) \in J_{\text{sub}}} (M_j - d) + \sum_{k: (k, :) \in J_{\text{sub}}} (N_k - d) \geq d |J_{\text{sub}}|, \quad \forall J_{\text{sub}} \subseteq J. \quad (11)
\]

Remark 3.6 (Backward Compatible to [12], [17], and [13]): If we further assume that \(d = 1\), then \(d |M_k|, d |N_k\) for all \(k \in \{1, \ldots, K\}\). In this case, Cor. 3.4 corresponds to that in [12]. Similarly, if we require both \(N_k\) and \(M_k\) are divisible by \(d\), Cor. 3.4 is reduced to the feasibility conditions given by [14], [15].

B. Proof of the Feasibility Conditions

1) Proof of Theorem 3.2. Note that the necessity of (4) and (6) is proved in [13]–[15]. We need to prove the necessity of (5).

Suppose Problem 1 is feasible. Without loss of generality, assume for a certain set \(J_{\text{sub}} \subseteq J\).

\[
\sum_{k: (k, :) \in J_{\text{sub}}} N_k = \max \left\{ \sum_{j: (-j) \in J_{\text{sub}}} M_j, \sum_{k: (k, :) \in J_{\text{sub}}} N_k \right\}. \quad (12)
\]

Then for \(J_{\text{sub}}\), (5) can be rewritten as:

\[
\sum_{k: (k, :) \in J_{\text{sub}}} N_k \geq \sum_{j: (-j) \in J_{\text{sub}}} d_j \quad (13)
\]

We will prove that if Problem 1 has a solution, (13) must be true. Denote \(T\) as the set of the indices which appears in \(J_{\text{sub}}^t\) as Tx index but not Rx index, i.e. \(T = \{ j_1, \ldots, j_m \} = \{ j : \exists k \text{ s.t. } (k, j) \in J_{\text{sub}}^t \} \) and \((j, k) \notin J_{\text{sub}}^t\), and denote \(R\) as the set of indices which appears in \(J_{\text{sub}}^t\) as Rx index, i.e. \(R = \{ k_1, \ldots, k_n \} = \{ k : \exists j \text{ s.t. } (k, j) \in J_{\text{sub}}^t\}\). Denote \(\{ U_k^t, V_k^t \}\) as one of the solution. Construct three matrices:

\[
V_T^* = \begin{bmatrix} V_{j_1}, 0, \cdots, 0 \\ 0, V_{j_2}, \cdots, 0 \\ \vdots \\ 0, 0, \cdots, V_{j_m} \end{bmatrix}, \quad U_R^* = \begin{bmatrix} U_{k_1}, 0, \cdots, 0 \\ 0, U_{k_2}, \cdots, 0 \\ \vdots \\ 0, 0, \cdots, U_{k_m} \end{bmatrix},
\]

\[
H_{J_{\text{sub}}} = \begin{bmatrix} H_{k_1 j_1}, H_{k_1 j_2}, \cdots, H_{k_1 j_m} \\ H_{k_2 j_1}, H_{k_2 j_2}, \cdots, H_{k_2 j_m} \\ \vdots \\ H_{k_n j_1}, H_{k_n j_2}, \cdots, H_{k_n j_m} \end{bmatrix}
\]

Then from (2) and (3), we have that:

\[
\dim(\text{span}(V_T^*)) = \sum_{j \in T} d_j, \quad \dim(\text{span}(U_R^*)) = \sum_{k \in R} d_k, \quad (14)
\]

\[ U_R^* H_{J_{\text{sub}}} V_T^* = 0. \quad (15) \]

From (12), \(\sum_{j \in T} M_j \leq \sum_{j: (-j) \in J_{\text{sub}}^t} M_j \leq \sum_{k \in R} N_k\), which means in \(J_{\text{sub}}^t\), the number of rows is no more than the number of columns. Further note that the elements of \(H_{J_{\text{sub}}^t}\) are independent random variables, we have that \(\lambda(H_{J_{\text{sub}}^t}) = \{0\}\) almost surely. Therefore

\[
\dim(\text{span}(H_{J_{\text{sub}}}, V_T^*)) = \dim(\text{span}(V_T^*)) = \sum_{j \in T} d_j \quad (16)
\]

almost surely. From (15), \(\dim(\text{span}(H_{J_{\text{sub}}}, V_T^*)) \perp \text{span}(U_R^*)\), hence we have:

\[
\sum_{k \in R} N_k \geq \dim(\text{span}(H_{J_{\text{sub}}}, V_T^*)) + \dim(\text{span}(U_R^*))
\]

\[
= \sum_{j \in T} d_j + \sum_{k \in R} d_k = \sum_{j: (-j) \in J_{\text{sub}}^t} d_j \quad (17)
\]

From (17), (13) is true. This completes the proof.

2) Proof of Theorem 3.2. The IA feasibility issue is challenging as there is no systematic tool to address the solvability issue of high-degree polynomial equation sets. In the following analysis, we first elaborate three lemmas. As illustrated in Fig. 2 these lemmas construct a new systematic tool that links linear independence to the solvability of polynomial equation sets. The newly developed tool is not only the key steps to handle the IA feasibility issue in this work, but also a good candidate of handling the solvability issue of sets of polynomial equations in general.

Lemma 3.1: (Linear Independence Leads to Algebraic Independence) Suppose \(K\) is an algebraically closed field. Consider \(L\) polynomials \(f_i \in K[x_1, x_2, \ldots, x_S], i \in \{1, \ldots, L\}\) which are given by: \(f_i = \sum_{j=1}^S h_{ij} x_j + g_i\), where \(g_i\) are polynomials consisting of terms with degree no less than 2. If the coefficient vectors \(h_i = [h_{i1}, h_{i2}, \ldots, h_{iS}]\) are linearly independent, then polynomials \(\{f_i\}\) are algebraically independent.

Proof: Please refer to Appendix A for the proof. \(\Box\)
Lemma 3.2: (Algebraic Independence is Invariant up to a Random Constant) Suppose \( K \) is an algebraically closed field. Polynomials \( f_i \in K[x_1, x_2, \ldots, x_S], i \in \{1, \ldots, L\} \) are algebraically independent, and \( c_i \) are independent random variables drawn from continuous distribution in \( K \). Then \( g_i = c_i + f_i \) are algebraically independent almost surely.

Proof: Please refer to Appendix [B] for the proof. \( \square \)

Lemma 3.3: (Algebraic Independence Leads to Non-empty Vanishing Set) Suppose \( K \) is an algebraically closed field. If polynomials \( f_i, i \in \{1, \ldots, L\} \) are algebraically independent, then the vanishing set of these polynomials, i.e., \( V(f_1, \ldots, f_L) = \{(x_1, \ldots, x_S) : f_i = 0, i \in \{1, \ldots, L\}\} \) is non-empty.

Proof: Please refer to Appendix [C] for the proof. \( \square \)

In the following analysis, we prove Thm. 3.2 by applying the new tool developed above. First we transfer the IA problem (Problem 1) into another equivalent form.

Lemma 3.4 (Problem Transformation): Problem 1 is equivalent to Problem 2 (defined below) almost surely.

Problem 2 (Transformed IA Processing): Find \( \{U_k, V_k\} \) such that \( \text{rank}(U_k) = \text{rank}(V_k) = d_k, \forall k \) and satisfy (3).

Proof: Please refer to Appendix [D] for the proof. \( \square \)

In Problem 2, to ensure that \( \text{rank}(U_k) = \text{rank}(V_k) = d_k \), it is sufficient to assume that the first \( d_k \times d_k \) submatrix of \( U_k, V_k \), denoted by \( U_k^{(1)}, V_k^{(1)} \), are invertible. Then we can define \( \tilde{U}_k \in \mathbb{C}^{(N_k-d_k) \times d_k}, \tilde{V}_j \in \mathbb{C}^{(M_j-d_j) \times d_j} \) as follows:

\[
\begin{bmatrix}
I_{d_k \times d_k} \\
\tilde{U}_k
\end{bmatrix} = U_k \begin{bmatrix} U_k^{(1)} \end{bmatrix}^{-1}, \quad \begin{bmatrix}
I_{d_j \times d_j} \\
\tilde{V}_j
\end{bmatrix} = V_j \begin{bmatrix} V_j^{(1)} \end{bmatrix}^{-1}.
\]

Then (3) is transformed into the following form

\[
f_{k,j,p,q} = h_{k,j}(p,q) + \sum_{n=1}^{N_k-d_k} h_{k,j}(d_k+n,q) \tilde{u}_k^{H}(n,p) + \sum_{m=1}^{M_j-d_j} h_{k,j}(p,d_j+m) \tilde{v}_j(m,q)
\]

\[
+ \sum_{n=1}^{N_k-d_k} \sum_{m=1}^{M_j-d_j} h_{k,j}(d_k+n,d_j+m) \tilde{u}_k^{H}(n,p) \tilde{v}_j(m,q)
\]

\[
= h_{k,j,p,q} \mathbf{v} + \sum_{n=1}^{N_k-d_k} \sum_{m=1}^{M_j-d_j} h_{k,j}(d_k+n,d_j+m) \tilde{u}_k^{H}(n,p) \tilde{v}_j(m,q)
\]

\[
= 0
\]

where \( h_{k,j}(p,q), \tilde{u}_k(p,q), \) and \( \tilde{v}_j(p,q) \) are the elements in the \( p \)-th row and \( q \)-th column of \( H_{k,j}, \tilde{U}_k \) and \( \tilde{V}_j \), respectively.

\[
v = [\tilde{u}_k^{H}(1,1), \tilde{u}_k^{H}(2,1), \ldots, \tilde{u}_k^{H}(N_k-d_k+1,1), \tilde{u}_k^{H}(1,2), \ldots, \tilde{u}_k^{H}(N_k-d_k+1,d_k), \ldots, \tilde{u}_k^{H}(1,1), \tilde{v}_j(2,1), \ldots, \tilde{v}_j(M_k-d_k+1,1), \tilde{v}_j(1,2), \ldots, \tilde{v}_j(M_k-d_k+1,d_k))]
\]

Substituting (19) to Lem. 3.1, 3.3, we can prove that Problem 1 has solution almost surely if \( H_{all} \) defined in Fig. 1 is full row rank.

3) Proof of Corollary 3.1 Note that \( H_{all} \in \mathbb{C}^{C \times V} \), where \( C = \sum_{k=1}^{K} \sum_{j=1}^{J} d_k d_j, V = \sum_{k=1}^{K} d_k (M_k + N_k + 2d_k) \). \( H_{all} \) is full row rank if and only if at least one of its \( C \times C \) submatrices has non-zero determinant. Therefore, the statement is proved if the following proposition holds:

**Proposition 3.1:** Under a network configuration \( \chi \), the determinant of a \( C \times C \) sub-matrix of \( H_{all} \) is either always zero or non-zero almost surely.

To prove Prop. 3.1, we first have the following lemma:

**Lemma 3.5:** Suppose \( x_1, \ldots, x_S \in \mathbb{C} \) are independent random variables drawn from continuous distribution, \( f \) is a non-constant polynomial in \( \mathbb{C}[x_1, \ldots, x_S] \). Then \( f(x_1, \ldots, x_S) \neq 0 \) almost surely, i.e. the polynomial evaluated at \( (x_1, \ldots, x_S) \) is non zero with probability 1.

**Proof:** When \( k = 1 \), from the Fundamental Theorem of Algebra [17], \( f(x_1) = 0 \) only has finite number of solutions. On the other hand, \( x_1 \) is drawn from continuous distribution. Hence \( f(x_1) \neq 0 \) almost surely.

For \( k \geq 2 \), the lemma can be proved by using mathematical induction w.r.t. \( k \). We omit the details for conciseness. \( \square \)

From the Leibniz formula [20, 6.1.1], the determinant of a \( C \times C \) sub-matrix of \( H_{all} \) can be written as a polynomial \( f \in \mathbb{C}[h_{k,j}(p,q)] \) with no constant term, where \( k \neq j \in \{1, \ldots, K\}, p \in \{1, \ldots, N_k\}, q \in \{1, \ldots, M_j\} \). Further note that the coefficients of \( f \) is determined by the configuration of the network \( \chi \). Hence, under a certain \( \chi \), \( f \) is either a zero polynomial or a non-constant polynomial. In the latter case, by applying Lem. 3.5, we have that \( f \neq 0 \) almost surely. This completes the proof.

4) Proof of Corollary 3.2 As illustrated in Fig. 3 from [8] and [9], after the scaling, each \( H_{ij}^{(1)} \) (or \( H_{ij}^{(2)} \)) is composed of repeating a submatrix with independent elements \( c_{ij}d_k \) (or \( cd_j \)) times. Denote the \( s \)-th time of appearance of this matrix as \( H_{ij}^{(1,s)}(s) \) (or \( H_{ij}^{(2,s)}(s) \)). Moreover, we can evenly partition every \( H_{ij}^{(1,s)}(s), H_{ij}^{(2,s)}(s) \) into \( c^2 \) independent blocks. Denote the \( l \)-th diagonal block in \( H_{ij}^{(1,s)}(s) \) (or \( H_{ij}^{(2,s)}(s) \)) as \( H_{ij}^{(1,s,l)}(s,l) \) (or \( H_{ij}^{(2,s,l)}(s,l) \)), \( l \in \{1, \ldots, c\} \). Rewritten \( H_{all} \) as a sum of two matrices, one consists of the diagonal blocks \( \{H_{ij}^{(1,s,l)}(s,l)\} \) and \( \{H_{ij}^{(2,s,l)}(s,l)\} \) and the other contains the rest of the blocks.

Denote the two matrices as \( H_{all}^{(1)} \) and \( H_{all}^{(2)} \), respectively.

Since \( H_{ij}^{(1)} \) and \( H_{ij}^{(2)} \) are independent, it is sufficient to show that \( H_{all}^{(1)} \) is full row rank. As illustrated in Fig. 3 by combining \( \{H_{ij}^{(1,l,s)}(s,l) : s \in \{l(l-1)d_k+1, l(l-1)d_k+2, \ldots, l(l-1)d_k\}\} \) with \( \{H_{ij}^{(1,l,s')} (s') : s' \in \{l(l-1)d_k+1, l(l-1)d_k+2, \ldots, l(l-1)d_k\}\} \), \( l, l' \in \{1, \ldots, c\} \), we obtain \( c^2 \) combinations. By collecting the blocks with the same combination index \((l, l')\) in different \( H_{ij}^{(1,l)} \) and \( H_{ij}^{(1,l')} \), we obtain \( c^2 \) submatrices identical to the \( H_{all} \) before scaling. Since these submatrices are full rank almost surely.
and are on different rows and columns of $H_{all}^D$, $H_{all}^D$ is full rank almost surely. This completes the proof.

5) Proof of Corollary 3.3 For notational convenience, we will use notation $(M \times N, d)^K$ to represent the configuration of a symmetric MIMO interference network, where the meaning of the letters are as the same those in Cor. 3.3.

The “only if” side can be easily derived from (6). We adopt the following procedures to prove the “if” side:

A. Construct one special category of channel state $\{H_{kj}\}$.

B. Show that $H_{all}$ is full rank almost surely under the special category of channel state.

C. From Cor. 3.1 if Procedure B is completed, $H_{all}$ is full rank almost surely and hence the corollary.

Now we start the detailed proof following the outline illustrated above. We first have two lemmas.

Lemma 3.6 (Sufficient Condition for Full Rankness):
Denote $H_{kj}^t = \text{span}\{h_{ijpq} : j \in \{1, \ldots, K\}, j \neq k, p, q \in \{1, \ldots, d\}\} \cap \mathcal{V}$, where $\mathcal{V} = \text{span}\left(\begin{pmatrix} 0_{D_{kk}} & D_{kk} \end{pmatrix}, D_{kk} = K(N-d)d$, $D_{kk} = K(M-d)d$. When $N \geq 2d$, $H_{all}$ is full row rank almost surely if the basis vectors of all $H_{kj}^t$, $k \in \{1, \ldots, K\}$ are linearly independent.

Proof: Please refer to Appendix E for the proof.

Lemma 3.7 (Full Rankness of Special Matrices): A matrix $H_{all}$ with the following structure is full rank almost surely.

S1. $H_{all}^D$ is composed of $d \times d$ blocks, each block is composed of $K \times K$ sub-blocks, and each sub-block is aggregated by $M - d$ number of $1 \times M - d$ vectors. Matrix 1 in Fig. 4 illustrates an example with $d = 2$, $K = 2$, $M = 4$.

S2. Denote the sub-blocks as $B_{ss'}kk'$, $s, s' \in \{1, \ldots, d\}$, $k, k' \in \{1, \ldots, K\}$, where $s, s'$ denote the vertical and horizontal position of the block, and $k, k'$ denote the vertical and horizontal position of the sub-block within the block (e.g. $B_{1212}$ in Fig. 4). All diagonal blocks are block-diagonal, i.e. $B_{ss'kk'} = 0$, if $k \neq k'$. Denote the $k$-th diagonal sub-block in block $s$ as $B_{sk}$ (e.g. $B_{12}$ in Fig. 4).

S3. The elements in every $B_{sk}$ are independent random variables drawn from continuous distribution.

S4. $B_{sk}$ is independent of all the diagonal sub-blocks with different sub-block index, i.e. $\{B_{sk}^{k'} : k' \neq k\}$ and all the sub-blocks in the same columns and rows, i.e. $\{B_{s's'kk'} : s' \neq s$ or $k' \neq k\}$. The vectors in the off-diagonal blocks are either 0, or independent of all diagonal sub-blocks, or repetition of a certain vector in the diagonal sub-blocks (positioned in different columns).

S5. Define diagonal sub-blocks $B_{sk}^D$ and $B_{sk'}^D$ are associated, if a certain vectors in sub-blocks $B_{s's'kk'}$ or $B_{s's'kk'}, s \neq s', k \neq k'$ is a repetition of a certain vector in the diagonal sub-blocks. Each diagonal sub-block $B_{sk}^D$ is associated with at most one diagonal sub-block in the neighboring sub-blocks with different sub-block index, i.e. $B_{sk}^{D_{(s-1)k}}$ and $B_{sk}^{D_{(s+1)k'}}$, for some $k', k'' \neq k$. Note that when $s = 1$ or $d$, each diagonal sub-block is associated with at most one sub-block.

\begin{alignat*}{2}
& \{B_{s's'kk'} : s' \neq s &\text{ or } k' \neq k\} \text{. The vectors in the off-diagonal blocks are either 0, or independent of all diagonal sub-blocks, or repetition of a certain vector in the diagonal sub-blocks (positioned in different columns).} \\
& \text{S5. Define diagonal sub-blocks } B_{sk}^D &\text{ and } B_{sk'}^D &\text{ are associated, if a certain vectors in sub-blocks } B_{s's'kk'} &\text{ or } B_{s's'kk'}, s \neq s', k \neq k' &\text{ is a repetition of a certain vector in the diagonal sub-blocks. Each diagonal sub-block } B_{sk}^D &\text{ is associated with at most one diagonal sub-block in the neighboring sub-blocks with different sub-block index, i.e. } B_{sk}^{D_{(s-1)k'}} &\text{ and } B_{sk}^{D_{(s+1)k''}} &\text{, for some } k', k'' \neq k. \text{ Note that when } s = 1 &\text{ or } d, &\text{ each diagonal sub-block is associated with at most one sub-block.}
\end{alignat*}
Fig. 5. Illustration of proving that $H_{\text{all}}$ is full rank in a $(7 \times 8, 3)^4$ network.

Fig. 6. Specify $\{H^V_{kj}\}$.

user indices $k, j$, i.e. index pairs $(k, j)$ and $(\mod(k + \delta), \mod(j + \delta))$ lead to the same $P(k, j)$ and $R(k, j)$, $\forall \delta \in \mathbb{Z}$. This property will help us to exploit the symmetry of the network configuration in the proof.

B. From (2), each $H^V_{kj}$ consists of $d$ independent $1 \times (N-d)$ vectors repeating for $d$ times. For notational convenience, denote these vectors as $h_{kj}(1) \sim h_{kj}(d)$ and denote their $s$-th time of appearance as the $s$-th block of $H^V_{kj}$. The small matrix below matrix (1) in Fig. 5 has given such an example. As illustrated by matrix (2) in Fig. 5 under the specification in Fig. 6, we can adopt row operations to remove the “1”s that reappear in the same columns. From Lem. 3.6 it is sufficient to prove that the row vectors which are occupied by the $s$-th block of $H^V_{kj}$ are linearly independent, where $s, k,$ and $j$ satisfy:

$$\begin{cases} \emptyset & \text{if } \mod(j-k, K) \leq \left\lfloor \frac{N}{d} \right\rfloor - 1, \\ \{ \mod(N, d)+1, \ldots, d \} & \text{if } \mod(j-k, K) = \left\lfloor \frac{N}{d} \right\rfloor, \\ \{ 1, \ldots, d \} & \text{otherwise.} \end{cases}$$

Also note that after the row operation, the $1 \sim (d - 1)$-th block of $H^V_{kj}$, $k = \mod(j - 2, K) + 1$ is replicated, taken a minus sign and moved to other rows. Denote these new submatrices as $\{H^V_{kj}\}, k = \mod(j - 2, K) + 1, j \in \{ 1, \ldots, K \}$. Now we can adopt Lem. 3.7 to prove the linear independence of the row vectors specified by (24). Specifically, for every $j \in \{ 1, \ldots, K \}$, select the following vectors:

- When $k = \mod(j - 2, K) + 1$: $h_{kj}(1) \sim h_{kj}(d-s)$ in the $s$-th block of $H^V_{kj}$, where $s \in \{ 1, \ldots, d-1 \}$.
- When $k = \mod(j - \left\lfloor \frac{N}{d} \right\rfloor, K) + 1$: $h_{kj}(d')$ in the $s$-th block of $H^V_{kj}$, where $d' = d + \mod(N, d) + 1 - s$, $s \in \{ \mod(N, d) + 1, \ldots, d \}$.
- When $k = \mod(j - \left\lfloor \frac{N}{d} \right\rfloor, 2 K) + 1$: $h_{kj}(d')$ in the $s$-th block of $H^V_{kj}$, where $d' = \max(1, \mod(N, d) + 1 - s)$, $s \in \{ 1, \ldots, d \}$.
- When $k = \mod(j - l, K) + 1$: $l \not\in \{ \left\lfloor \frac{N}{d} \right\rfloor + 1, \ldots, K \}$: all vectors in $H^V_{kj}$.

Then as illustrated by the small matrices on the right side of Fig. 5 by adopting this selection mechanism, we have chosen $Kd(M-d)$ vectors, which form $Kd$ number of $(M-d) \times (M-d)$ submatrices positioned on different rows and columns. Denote these submatrices as $B_{kj}$, where $s \in \{ 1, \ldots, d \}$ and $j \in \{ 1, \ldots, K \}$ represent the block and user index, respectively. Map $B_{kj}$ to $B^V_{kj}$ in Lem. 3.7 where $s$ and $s'$ satisfy: $s = \mod(d + d' - s, \mod(M, d) - d + 1) + 1$. As $gcd(M, d) = 1$, this is a one to one mapping. Since the submatrices are positioned on different rows and columns, we can move them to the principle diagonal and verify that the structures required in Lem. 3.7 are satisfied. This completes the proof.

6) Proof of Corollary 3.4 We first prove some key lemmas and then turn to the main flow of the proof.

Lemma 3.8 (Sufficient Conditions for IA Feasibility): If there exists a set of binary variables $\{ c_{kj}, c_{kjpq} \} \in \{ 0, 1 \}$, $k, j \in \{ 1, \ldots, K \}$, $k \neq j$, $p \in \{ 1, \ldots, d_k \}$, $q \in \{ 1, \ldots, d_j \}$ that satisfy the following constraints, Problem I has solution almost surely.

$$c_{kj} + c_{kjpq} = 1,\tag{25}$$

$$\sum_{j=1, j \neq k}^{K} \sum_{q=1}^{d_j} c_{kjpq} \leq N_k - d_k, \forall k,\tag{26}$$

$$\sum_{k=1, k \neq j}^{K} \sum_{p=1}^{d_j} c_{kjpq} \leq M_j - d_j, \forall j.\tag{27}$$
\[ c_{kj1q}^* = ... = c_{kjdq^*}^* \quad \forall k,j,q, \text{ OR } \]
\[ c_{kj1p}^* = ... = c_{kjdp^*}^* \quad \forall k,j,p. \quad (28) \]

Proof: Please refer to Appendix C for the proof. \qed

Remark 3.7 (Interpretation of \( c_{kj1q}^* \), \( c_{kj1p}^* \)): The binary variables \( c_{kj1q}^* \) \( c_{kj1p}^* \) represent a constraint allocation policy. An IA constraint \( f_{kjpq} = 0 \) (defined in (19)) can be assigned to transceivers with non-zero coefficients in \( f_{kjpq} \), i.e. \( \tilde{u}_{kp} \in C^{1 \times (N_r - d_q)} \) or \( \tilde{v}_{jq} \in C^{1 \times (N_t - d_j)} \). Here \( \tilde{u}_{kp} \) \( \tilde{v}_{jq} \) denote the \( q \) \( p \)-th column of \( \tilde{U}_k \) \( \tilde{V}_j \). \( c_{kj1q}^* = 1 \) \( c_{kj1p}^* = 1 \) means that the IA constraint \( f_{kjpq} = 0 \) is assigned to the decorrelator (precoder) for the \( p \) \( q \)-th stream at Rx \( k \) \( (Tx \ j) \).

Remark 3.8 (Meaning of Constraints in Lem. 3.8):\]

• (25): Each IA constraint \( f_{kjpq} = 0 \) is assigned once and only once.
• (26): The total number of constraints assigned to the decorrelator of any stream, i.e. \( \tilde{u}_{kp} \) is no more than the length of this decorrelator, i.e. size\( \tilde{u}_{kp} \) = \( N_k - d_k \).
• (27): The dual version of (26).
• (28): The constraint assignment policy \( \{ c_{kj1q}^*, c_{kj1p}^* \} \) is symmetric w.r.t. Rx side stream index \( p \) or Tx side stream index \( q \). \qed

The following lemma illustrate the relation between the sufficient conditions proposed in Lem. 3.8 and the necessary conditions proposed in Thm. 3.1.

Lemma 3.9 (Necessary Conditions of IA Feasibility): A network configuration \( \chi \) satisfies the necessary feasibility condition (6), if and only if there exists a set of binary variables \( \{ c_{kj1q}^*, c_{kj1p}^* \in \{0,1\} \} \), \( k,j \in \{1, ..., K\} \), \( k \neq j \), \( p \in \{1, ..., d_k\} \), \( q \in \{1, ..., d_j\} \) that satisfy (25)–(27).

Proof: Please refer to Appendix D for the proof. \qed

Remark 3.9 (Insight of Lem. 3.8, 3.9): Prior works studying the IA feasibility problem on MIMO interference networks have shown that the properness condition, i.e. (6), is the major factor that characterizes the IA feasibility conditions. However, (6) contains \( O(2^K^2) \) number of correlated inequalities. Such a complicated condition is hard to trace in both analysis and practice.

Lem. 3.9 enables us to significantly simplify (6). By exploiting the idea of constraint allocation, Lem. 3.9 converts (6) to (25)–(27), which consist of only \( O(K) \) number of constraints. Lem. 3.8 shows that with an additional requirement (28) on the constraint allocation policy \( \{ c_{kj1q}^*, c_{kj1p}^* \} \), the IA feasibility is guaranteed.

Now we turn to the main flow of the proof for Cor. 3.4. The “only if” side is directly derived from (6). The “if” side is completed by adopting Lem. 3.8 Please refer to Appendix E for the details of constructing \( \{ c_{kj1q}^*, c_{kj1p}^* \} \) which satisfy (25)–(28).

IV. SUMMARY AND FUTURE WORK

This work further consolidates the theoretical basis of IA. We have proved a sufficient condition of IA feasibility with which applies to MIMO interference networks with general configurations and discovered that IA feasibility is preserved when scaling the network. Further analysis show that the sufficient condition and the necessary conditions coincide in a wide range of network configurations and provide some simple analytical conditions. These results unify and extend the pertaining theoretical works in the literature [12]–[15] and facilitate future analysis on MIMO interference networks.

Despite the progress made in the prior works and this work, the issue of IA feasibility is yet not fully solved. In particular, there may be gaps between the necessary conditions in Thm. 3.1 and the sufficient condition in Thm. 3.2 and therefore the exact feasibility conditions of IA are still not determined in general. Merging the gap between the necessary and the sufficient side shall be the direction for future works.

APPENDICES

A. Proof of Lemma 3.1

When vectors \( \{ h_i \} \) are linearly independent, we have that \( L \leq S \). Note that if the lemma holds when \( L = S \), it must hold in general. We will use contradiction to prove the statement. Suppose \( f_i, \ i \in \{1, 2, ..., L\} \) are algebraically dependent. Then from the definition, there must exist a nonzero polynomial \( p \) such that \( p(f_1, f_2, ..., f_S) = 0 \). Without loss of generality, denote \( p = p_0 + p_1 + ... + p_D \), where \( p_d \) contains all the \( d \)-th degree terms in \( p, D \in \mathbb{N} \). Then we have:

\[
p(f_1, f_2, ..., f_S) = p_0 + p_1 \sum_{j=1}^{S} h_{ij} x_j + ... + p_D \sum_{j=1}^{S} h_{ij} x_j = 0 \quad (29)
\]

Note that all the terms in \((p_1(g_1, ..., g_S) + \sum_{d=2}^{D} p_d(f_1, f_2, ..., f_S))\) have degree no less than 2, from (29), \( p_1(\sum_{j=1}^{S} h_{ij} x_j, ..., \sum_{j=1}^{S} h_{ij} x_j) = 0, \forall x_1, ..., x_j \in \mathbb{K} \). Denote \( y_i = \sum_{j=1}^{S} h_{ij} x_j \), we have that:

\[
p_1(y_1, ..., y_S) = 0. \quad (30)
\]

Note that the coefficient vectors \( h_i \) are linearly independent, \( [x_1, ..., x_S] \rightarrow [y_1, ..., y_S] \) is a bijective linear map. Therefore, \( \{y_1, ..., y_S\} \cong \{x_1, ..., x_S\} = \mathbb{K}^S \). Hence, from (30), we have that \( \mathcal{V}(p_1) = \{y_1, ..., y_S\} \cong \mathbb{K}^S \), which means \( p_1 \) must be a zero polynomial.

Similarly, when \( p_1 \) is a zero polynomial, by analyzing the coefficients of the second order terms, we have that \( \mathcal{V}(p_2) \cong \mathbb{K}^S \) and therefore \( p_2 \) is also a zero polynomial. By using mathematical induction, we can show that \( p_1, p_2, ..., p_D \) are zero polynomials and hence \( p \) a zero polynomial, which is a contradiction with the assumption that \( f_i, \ i \in \{1, 2, ..., L\} \) are algebraically dependent. This completes the proof.

B. Proof of Lemma 3.2

We first prove that \( g_1, f_2, ..., f_L \) are algebraically independent. Then the Lemma can be proved by repeating the same trick \( L \) times. We will use contradiction to prove
the statement. Suppose $g_1, f_2, ..., f_L$ are algebraically dependent, i.e. there exists a non-zero polynomial $p$ such that $p(g_1, f_2, ..., f_L) = 0$. Without loss of generality, denote $p(g_1, f_2, ..., f_L) = \sum_{d=0}^{D} A_d p_d(f_2, ..., f_L), D \in \mathbb{N}$, where $p_d$ is a polynomial function of $f_2 \sim f_L$. Then we can define polynomial $p^f(f_1, f_2, ..., f_L) = \sum_{d=0}^{D} A_d p_d + c_1 \sum_{d=0}^{D} \sum_{s=0}^{d} \binom{d}{s} c_1^{(d-s)} p_d(f_2, ..., f_L)$ where $\binom{s}{d}$ denotes the number of $s$-combination of a set with $d$ elements. Note that $\sum_{d=1}^{D} A_d p_d = p(f_1, ..., f_L)$ is nonzero, and $c_1$ is independent of the coefficients in $p_d$, we have that $p^f$ is nonzero almost surely. However, $p^f(f_1, f_2, ..., f_L) = 0$, which contradicts with the assumption that $f_1, ..., f_L$ are algebraically independent. This completes the proof.

C. Proof of Lemma 3.3

Since $\{f_i\}$ are algebraically independent, from Thm. 0.4, Lecture 2], $K[f_1, ..., f_L] \cong K[y_1, ..., y_L]$, where $y_1, ..., y_L$ are variables in $K$. Hence, $(f_1, ..., f_L) \cong (y_1, ..., y_L)$, where $(z_1, ..., z_L)$ denotes the ideal generated by $z_1, ..., z_L$. Note that ideal $(z_1, ..., z_L)$ is proper, i.e. does not contain $1$, so is ideal $(f_1, ..., f_L)$. From Hilbert’s Nullstellensatz Theorem [22] Thm. 3.1, Chap. 1], $\mathcal{V}(f_1, ..., f_L)$ is non-empty.

D. Proof of Lemma 3.4

Firstly, it is easy to see that a solution of Problem 1 is a solution of Problem 2. Conversely, since the channel state of the direct links $\{H_{kk}\}$ are full rank with probability 1 and are independent of that of cross links $\{H_{kj}\}, k \neq j$, a solution of Problem 2 is also a solution of Problem 1 with probability 1.

E. Proof of Lemma 3.6

We first have two lemmas.

Lemma E.1: In $H_{all}$, the row vectors that are related to a same Rx are linearly independent almost surely, i.e. for every $k \in \{1, ..., K\}$, vectors $H_{kj, pq}$, $j \in \{1, ..., K\}, j \neq k, p, q \in \{1, ..., d\}$ are linearly independent almost surely.

Proof: From [8], and the fact $M - d \geq d$, we have that every submatrix $H_{kj, pq}$ is full rank almost surely. Since for a given $k$, submatrices $H_{kj, j}, j \in \{1, ..., K\}, j \neq k$ position on different rows and columns in $H_{all}$, the lemma is proved.

Lemma E.2: As illustrated in Fig. 5, we denote $H_{kj, pq}$ as the vector consists of the first $K(N-k)d$ elements of $H_{kj, pq}$. For all $k, j, k^1, j^1 \in \{1, ..., K\}, k \neq k^1, j, p, p^1 \in \{1, ..., d\}, q, q^1 \in \{1, ..., d\}$, $H_{kj, pq} \perp H_{kj^1, p^1 q^1}$.

Proof: Straight forward from the structure of $H_{all}$. We will prove the lemma by proving its converse-negative proposition. From Lemma E.1 if $H_{all}$ is not full row rank, there must exists a non-zero vector $\mathbf{h}$ and set $A, B \subset \{1, ..., K\}$, $A \cap B = \emptyset$ such that $\mathbf{h} \in (\cup_{k \in A} \mathcal{H}_k) \cap (\cup_{k \in B} \mathcal{H}_k)$, where $\mathcal{H}_k = \text{span} \{b_{kj, pq} \mid j \in \{1, ..., K\}, j \neq k, p, q \in \{1, ..., d\}\}$. Furthermore, from Lem. E.2 and the fact that $A \cap B = \emptyset$, we have that the first $K(N-d)d$ elements of $\mathbf{h}$ must be 0. By combining this fact with (33), we have that $\mathbf{h} \in (\cup_{k \in A} \mathcal{H}_k) \cap (\cup_{k \in B} \mathcal{H}_k)$, which means the basis vectors of $\mathcal{H}_k, k \in A \cup B$ are linearly dependent. This completes the proof.

F. Proof of Lemma 3.7

As illustrated by matrix $\circlearrowleft$ and $\circlearrowupright$ in Fig. 4, we can separate $H_{all}$ into two matrices, one consists of the diagonal sub-blocks and sub-blocks that are not independent of the diagonal blocks and the other consists of the sub-blocks that are independent of the diagonal sub-blocks. It is sufficient to show that the first matrix is full rank almost surely. From S3, each diagonal block is full rank almost surely. Hence, as illustrated by matrix $\circlearrowleft$ in Fig. 4, we can sequentially use row operation to make sub-blocks $\{B_{(k-1)dk'}\}, \{B_{(k-2)dk'}\}, ..., \{B_{2dk'}\}$ equal to 0 and make the matrix block upper-triangular. Noticing the association pattern S5, and the inter-block independence property S4, these operations preserves the block diagonal structure S2 and the full rankness of the diagonal sub-blocks. Then we can further adopt row operation to make the matrix block diagonal, e.g. matrix $\circlearrowleft$ in Fig. 4. Since each sub-block is full rank almost surely, the entire matrix is full rank almost surely.

G. Proof of Lemma 3.8

1) Illustration of the proof: We first illustrate the outline of the proof via an example and give out the rigorous proof in the next subsection.

Consider a 3-pairs MIMO interference network with configuration $\chi = \{(2, 2, 1), (2, 2, 1), (4, 2, 2)\}$. The constraint allocation $\{c_{kj, pq}^f, c_{kj, pq}^g\}$ is given by (34).

\[
\begin{align*}
c_{1211}^f & = c_{2111}^f = c_{3111}^f = c_{3221}^f = 1 \\
c_{1211}^g & = c_{2111}^g = c_{3111}^g = c_{3221}^g = 0 \\
c_{1211}^g & = c_{2111}^g = c_{3111}^g = c_{3221}^g = c_{3212}^g = c_{4212}^g = 1
\end{align*}
\]

(34)

From Thm. 3.2 to prove the lemma, we only need to show that $H_{all}$ is full rank row almost surely.

As illustrated by Fig. 4, we consider the matrix $H_{all}$ (we have rearranged the order of the rows for clearer illustration). In this network, we have 10 polynomials in 19 and 10 variables in $U_k, V_j$. Hence $H_{all}$ is a 10 \times 10 matrix. We need to prove that $H_{all}$ is nonsingular, i.e. det ($H_{all}$) $\neq 0$ almost surely.

The major properties of $H_{all}$ that lead to its nonsingularity are labeled in Fig. 7. We first carefully arrange the order of vectors $\{b_{kj, pq}\}$. In particular, index sequences $(k, j, p, q)$ that satisfy $c_{kj, pq}^f = 1$ or $c_{kj, pq}^g = 1$ are placed in the upper and lower part of $H_{all}$, respectively. We partition $H_{all}$ by rows according to whether $c_{kj, pq}^f = 1$ or $c_{kj, pq}^g = 1$, and by columns according to whether the column is occupied by $\{H_{kj}^U\}$ or $\{H_{kj}^V\}$. Then as illustrated by Label A in Fig. 7. $H_{all}$ is partitioned into four submatrices. $H_{all}^U$ and $H_{all}^V$ are block-diagonal as we have reordered the rows in $H_{all}$. As highlighted

\[
\mathbf{h} \in (\cup_{k \in A} \mathcal{H}_k) \cap (\cup_{k \in B} \mathcal{H}_k),
\]

(32)
by Label C, all the diagonal blocks of $H_{11}^{all}$, $H_{22}^{all}$ are full rank almost surely. Thus we have $H_{11}^{all}$, $H_{22}^{all}$ are nonsingular almost surely, i.e. $\det H_{11}^{all} \neq 0$, $\det H_{22}^{all} \neq 0$, almost surely.

From condition (25), if an element $h_{kj}(p, q)$ appears in $H_{22}^{all}$, it will not appear in any other sub-matrices of $H_{all}$. Hence, as illustrated by Label D in Fig. 7, $H_{22}^{all}$ is independent of the other three submatrices. Then from the Leibniz formula, we have that $\det(H_{all}) \neq 0$ holds almost surely.

2) Extending to General Configurations: We will show that properties of $H_{all}$ illustrated by Labels A–D in Fig. 4 hold for generic configurations.

Denote $\{c_{kjpq}^+, c_{kjpq}^-\}$ as a set binary variables that satisfy (25)–(28). Without loss of generality, suppose condition (28) holds for $\{c_{kjpq}^+\}$.

Reorder the rows of $H_{all}$ such that the row vectors which satisfy $\{h_{kj}(p, q) : c_{kjpq}^+ = 1\}$ appear in the upper part of the matrix. To show that $H_{all}$ is full row rank, we need to show there exists a sub-matrix $H_{11}^{all} \in \mathbb{C}^{(\sum_{k=1}^{K} \sum_{j=1}^{r(j)} d_k) \times (\sum_{k=1}^{K} \sum_{j=1}^{r(j)} d_k)}$ of $H_{all}$, whose determinant is non-zero almost surely. Construct $H_{11}^{all}$ by removing the columns which contain the coefficients of $\tilde{u}_k(p, q)$, $\tilde{v}_j(p^l, q^l)$, where $k$, $j$, $q$, $q^l$, $p$, and $p^l$ satisfy:

$$1 + c_{kj}^+ \leq p \leq N_k - d_{kj},$$
$$1 + c_{lj}^+ \leq l \leq M_j - d_{lj},$$

where $c_{kj}^+ = \sum_{k=1}^{K} \sum_{j=1}^{r(j)} d_k c_{kjpq}^+$, $c_{lj}^+ = \sum_{l=1}^{L} \sum_{j=1}^{r(j)} d_l c_{ljpq}^+$.

In the following analysis, we will partition $H_{all}$ in the same way as that in the example above and show that the major properties labeled in Fig. 7 still hold.

- **$H_{11}^{all}$ is full rank almost surely**: Consider the $1 \sim c_{11}^+$ columns of $H_{11}^{all}$. From (35), these are also the first $c_{11}^+$ columns of $H_{11}^{all}$ because $\{h_{kj}(p, q) : c_{kjpq}^+ = 1\}$ appears in the upper part of the matrix. Hence, from the form of vectors $\{h_{kj}(p, q)\}$, we have that elements in these columns are non-vanishing if and only if index $k = 1$, $j = 1$. In $H_{11}^{all}$, only the first $c_{11}^+$ rows are non-vanishing. Repeat the same analysis for other columns and we can show that $H_{11}^{all}$ is a $\sum_{k=1}^{K} \sum_{p=1}^{d_k} c_{kp}^+ \times \sum_{k=1}^{K} \sum_{p=1}^{d_k} c_{kp}^+$ block diagonal matrix, with diagonal block sizes $c_{11}^+, \ldots, c_{d_1}^+, \ldots, c_{d_N}^+$, respectively. From Fig. 1 (8), and 9, we have that the elements in a same diagonal blocks are independent of each other, hence $\det H_{11}^{all} \neq 0$ almost surely.

- **$H_{22}^{all}$ is full rank almost surely**: Using the analysis similar to above, we can show that $H_{22}^{all}$ is also block-diagonal and $\det H_{22}^{all} \neq 0$ almost surely.

- **$H_{22}^{all}$ is independent of $H_{11}^{all}$, $H_{22}^{all}$, and $H_{22}^{all}$** From Fig. 1 (8), and 9, an element $h_{kj}(p, d_j + s)$, $p \in \{1, \ldots, d_k\}$, $s \in \{1, \ldots, M_j - d_j\}$ only appears in vectors $h_{kjpq}^1, \ldots, h_{kjpq}^d$. Hence condition (28) assure that if $h_{kj}(p, d_j + s)$ appears in $H_{22}^{all}$, it appears in neither of the other three sub-matrices. This proves that $H_{22}^{all}$ is independent of $H_{11}^{all}$, $H_{22}^{all}$, and $H_{22}^{all}$.

The three facts above show that $\det (H_{all} \dagger) \neq 0$ almost surely. This completes the proof.

**H. Proof of Lemma 3.9**

We first prove the “only if” side. Denote $\{c_{kjpq}^+, c_{kjpq}^-\}$ as a set of binary variables that satisfy (25)–(27). Then we have:

$$\sum_{j=1}^{M_j} d_j (M_j - d_j) + \sum_{k=1}^{K} d_k (N_k - d_k) \geq \sum_{j=1}^{M_j} d_j (M_j - d_j) + \sum_{k=1}^{K} d_k (N_k - d_k) \geq \sum_{(k,j) \in \mathcal{J}_{sub}} \sum_{p=1}^{r(k)} (c_{kjpq}^+ + c_{kjpq}^-)$$

$$= \sum_{(k,j) \in \mathcal{J}_{sub}} d_k d_j \geq 0 \quad (38)$$

For $\forall J_{sub}$, where (37) is true due to (26), (27), and (38) is given by (25). This completes the “only if” side of the proof.

Then we turn to the “if” side. We adopt a constructive approach. In following algorithm 1, we will propose a method to construct the binary variables $\{c_{kjpq}^+, c_{kjpq}^-\}$ and show that when conditions (9) is true, the binary variables $\{c_{kjpq}^+, c_{kjpq}^-\}$ constructed by Alg. 1 satisfy (25)–(27).

We first define two notions which will be used in the algorithm. To indicate how far the constraint assignment policy $\{c_{kjpq}^+, c_{kjpq}^-\}$ is from satisfying constraints (26), (27), we define:

**Definition 1 (Constraint Pressure):**

$$P_{kq}^+ \triangleq M_j - d_j - \sum_{x \neq y} d_{kjpq}^+, P_{kq}^- \triangleq N_k - d_k - \sum_{x \neq y} d_{kjpq}^- \quad (39)$$

To update the constraint assignment policy, we introduce the following data structure.

**Definition 2 (Pressure Transfer Tree (PTT))**: As illustrated by Fig. 4A, define a weighted tree data structure with the following properties:

- The weight of the nodes in this tree is given by the constraint pressure, i.e. $\{P_{kq}^+, P_{kq}^-\}$.

Note that this algorithm may not be the only way to construct $\{c_{kjpq}^+, c_{kjpq}^-\}$.
- The constraint pressure of a parent node and its child nodes have different superscript, i.e. $t$ or $r$.
- The link strength between two nodes, e.g. $P_{jq}$ and $P_{kq}^r$ is given by $c_{kjpq}^r$, if $P_{jq}$ is the parent node, or $c_{kjpq}$, if $P_{kq}$ is the parent node.

**Algorithm 1** (Construct $\{c_{kjpq}^r, c_{kjpq}^r\}$):

- **Initialize the constraint allocation**: Randomly generate a constraint allocation policy, i.e., $\{c_{kjpq}^r, c_{kjpq}^r\}$ such that: $c_{kjpq}^r, c_{kjpq}^r \in \{0, 1\}$, $c_{kjpq}^r + c_{kjpq}^r = 1$, $k, j \in \{1, 2, ..., K\}$, $p \in \{1, ..., d_k\}$, $q \in \{1, ..., d_j\}$. Calculate $\{P_{jq}, P_{kq}\}$ according to (39).

- **Update the constraint allocation policy**: While there exist “overloaded streams”, i.e. $P_{jq}^t < 0$ or $P_{kq}^r < 0$, do the following to update $\{c_{kjpq}^r, c_{kjpq}^r\}$:
  - **A. Initialization**: Select a negative pressure, e.g. $P_{jq}^t < 0$. Set $P_{jq}^t$ to be the root node of a PTT.
  - **B. Add Leaf nodes to the pressure transfer tree**: For every leaf node (i.e. nodes without child nodes) e.g. $P_{jq}^t$, with depths equal to the height of the tree (i.e. the nodes at the bottom in Fig. 8). For every $k \in \{1, 2, ..., K\}$, $p \in \{1, ..., d_k\}$: If $c_{kjpq}^r = 1$, add $P_{kq}^r$ as a child node of $P_{jq}^t$.
  - **C. Transfer pressure from root to leaf nodes**: For every leaf node just added to the tree in Step B with positive pressure, i.e. $P_{jq}^t$ (or $P_{kq}^r$) > 0, transfer pressure from the root to these leafs by using $\{c_{kjpq}^r, c_{kjpq}^r\}$. For instance, as illustrated in Fig. 8B, $P_{jq}^t, P_{kq}^r, \{c_{kjpq}^r = 1 \}$ $\rightarrow$ $P_{j1}^t, P_{k1}^r, \{c_{kjpq}^r = 1 \}$ is a root-to-leaf branch of the tree (red lines). Transfer pressure from $P_{jq}^t$ to $P_{kq}^r$ by setting: $c_{kjpq}^r = 0, c_{kjpq}^r = 1$, $c_{kjpq}^r = 0, c_{kjpq}^r = 1$. Hence we have $P_{jq}^t$ is increased by 1 and $P_{kq}^r$ is reduced by 1. This operation can also be done for the green line in Fig 8B.
  - **D. Remove the “depleted” links and “neutralized” roots**:
    * If the strength of a link, i.e. $c_{kjpq}^r$ or $c_{kjpq}$ becomes 0 after Step C: Separate the subtree rooted from the child node of this link from the original tree.
    * If the root of a pressure transfer tree (including the subtrees just separated from the original tree) is nonnegative, remove the root and hence the subtrees rooted from each child node of the root become new trees. Repeat this process until all roots are negative. For each newly generated pressure transfer tree, repeat Steps B–D (Please refer to Fig. 9C for an example).

- **E. Exit Conditions**: Repeat Steps A–D until one of the following cases appears.
  - **Case 1**: All trees become empty.
  - **Case 2**: No new leaf node can be added for any of the non-empty trees in Step B.

Set $\{c_{kjpq}^r, c_{kjpq}^r\}$ to be the current value of $\{c_{kjpq}^r, c_{kjpq}^r\}$. Exit the algorithm. □

Note that if Alg. 1 exits with Case 1, we have that $M_j - d_j - \sum_{k=1}^{K} \sum_{p=1}^{d_k} c_{kjpq}^r \geq 0$, and $N_k - d_k - \sum_{j=1}^{K} \sum_{q=1}^{d_j} c_{kjpq}^r \geq 0$, $\forall k, j, p, q$, which lead to (6). Hence to prove the “if” side, we only need to prove the following proposition:

**Proposition H.1 (Exit State of Alg. 7)**: When (6) is true, Alg. 1 always exits with Case 1.

We prove Prop. H.1 by contradiction. (6) is equivalent to the following inequalities:

$$\sum_{j \in \mathbb{J}} (M_j - d_j) + \sum_{k \in \mathbb{K}} (N_k - d_k) \geq |\mathcal{L}_{sub}|, \forall \mathcal{L}_{sub} \subseteq \mathcal{L}$$

where $\mathcal{L} = \{(k, j, p, q) : k, j \in \{1, ..., K\}, k \neq j, p \in \{1, ..., d_k\}, q \in \{1, ..., d_j\}, (j, j, q) \in (k, r, p) \}$ in $\mathcal{L}_{sub}$ denotes that there exists $k, p, q$ such that $(k, j, p, q)$ is in $\mathcal{L}_{sub}$. If Alg. 1 exits with Case 2, from the exit condition, there must exist no non-empty pressure transfer tree such that:

- Root node has negative pressure.
- All other nodes are non-positive. This is because positive nodes are either “neutralized” by the root in Step C or separated from the tree in Step D.
- No other nodes can be added to the tree, which implies $c_{kjpq}^r = 0$ and $c_{kjpq}^r = 0$ for any $P_{jq}^t$, $P_{kq}^r$ in the tree and $P_{kq}^r$ not in the tree.

Hence, set $\mathcal{L}_{sub}$ in (40) to be $\{(k, j, p, q) : k, k \in \{1, ..., K\}, k \neq j, p \in \{1, ..., d_k\}, q \in \{1, ..., d_j\}\}$ to construct all trees. Repeat this process until all roots become new trees. Repeat this process until all roots are negative. For each newly generated pressure transfer tree, repeat Steps B–D (Please refer to Fig. 9C for an example).

- **I. Construct $\{c_{kjpq}^r, c_{kjpq}^r\}$ to Prove Corollary 3.4**

Without loss of generality, assume $d(N_k, \forall k$. Modify Alg. 1 in Appendix H to construct $\{c_{kjpq}^r, c_{kjpq}^r\}$.

**Algorithm 2** (Variation of Algorithm 7): Adopt Alg. 1 with the following modifications:

- In the Initialization Step: set $c_{kjp1} = 0 = c_{kj1p}$.
- In Step C: All pressure transfer operations must be symmetric w.r.t to index $q$, i.e. the operations on $c_{kjq}$ ($c_{kjp}^r$, $c_{kjp}^r$) must be the same. □

Suppose Prop. H.1 still holds for Alg. 2 Then the output of Alg. 2 ($\{c_{kjpq}^r, c_{kjpq}^r\}$) satisfies (25)–(28). Therefore, we focus on proving Prop. H.1.

From (39), after initialization, we have that

$$P_{j1}^t = ... = P_{jd_j}^t, d|P_{jq}^t, \forall n, q.$$ (42)

Since all $c_{kjpq}^r, c_{kjpq}^r$, and $P_{jq}^t$ are symmetric w.r.t. to index $q$, after we perform Steps A, B of the constraint updating
process, the pressure transfer trees are also symmetric w.r.t. to index \( q \). Further note that \( \partial_{(p,q)} \) in Step C, the symmetric operation is always feasible. As a result, we can follow the analysis used in Appendix H, and prove Prop H.1.
