A COMPLETE CHARACTERIZATION OF THE GAP BETWEEN
CONVEXITY AND SOS-CONVEXITY

AMIR ALI AHMADI† AND PABLO A. PARRILO‡

Abstract. Our first contribution in this paper is to prove that three natural sum of squares
(sos) based sufficient conditions for convexity of polynomials, via the definition of convexity, its first
order characterization, and its second order characterization, are equivalent. These three equivalent
algebraic conditions, henceforth referred to as sos-convexity, can be checked by semidefinite pro-
gramming, whereas deciding convexity is NP-hard. If we denote the set of convex and sos-convex
polynomials in \( n \) variables of degree \( d \) with \( \mathcal{C}_{n,d} \) and \( \mathcal{\Sigma C}_{n,d} \) respectively, then our main contribution
is to prove that \( \mathcal{C}_{n,d} = \mathcal{\Sigma C}_{n,d} \) if and only if \( n = 1 \) or \( d = 2 \) or \((n, d) = (2, 4)\). We also present a
complete characterization for forms (homogeneous polynomials) except for the case \((n, d) = (3, 4)\).
To prove these results, we present in particular explicit
examples of polynomials in \( \mathcal{\tilde{C}}_{2,6} \setminus \mathcal{\tilde{\Sigma}}_{2,6} \) and \( \mathcal{\tilde{C}}_{3,4} \setminus \mathcal{\tilde{\Sigma}}_{3,4} \) and forms in \( \mathcal{C}_{3,6} \setminus \mathcal{\Sigma C}_{3,6} \) and \( \mathcal{C}_{4,4} \setminus \mathcal{\Sigma C}_{4,4} \),
and a general procedure for constructing forms in \( \mathcal{C}_{n,d+2} \setminus \mathcal{\Sigma C}_{n,d+2} \) from nonnegative but not sos
forms in \( n \) variables and degree \( d \). Although for disparate reasons, the remarkable outcome is that
convex polynomials (resp., forms) are sos-convex exactly in cases where nonnegative polynomials
(resp., forms) are sums of squares, as characterized by Hilbert.

Key words. convexity, sum of squares, semidefinite programming

DOI. 10.1137/110856010

1. Introduction.

1.1. Nonnegativity and sum of squares. One of the cornerstones of real
algebraic geometry is Hilbert’s seminal paper of 1888 [22], where he gives a complete
characterization of the degrees and dimensions for which nonnegative polynomials can
be written as sums of squares (sos) of polynomials. In particular, Hilbert proves in [22]
that there exist nonnegative polynomials that are not sum of squares, although explicit
examples of such polynomials appeared only about 80 years later and the study of the
gap between nonnegative and sums of squares polynomials continues to be an active
area of research to this day.

Motivated by a wealth of new applications and a modern viewpoint that empha-
sizes efficient computation, there has also been a great deal of recent interest from
the optimization community in the representation of nonnegative polynomials as sos.
Indeed, many fundamental problems in applied and computational mathematics can
be reformulated as either deciding whether certain polynomials are nonnegative or
searching over a family of nonnegative polynomials. It is well-known, however, that if
the degree of the polynomial is four or larger, deciding nonnegativity is an NP-hard
problem. (This follows, e.g., as an immediate corollary of NP-hardness of deciding
matrix copositivity [30].) On the other hand, it is also well-known that deciding whether a polynomial can be written as an sum of squares can be reduced to solving a semidefinite program, for which efficient algorithms, e.g., based on interior point methods, are available. The general machinery of the so-called sos relaxation therefore has been to replace the intractable nonnegativity requirements with the more tractable sum of squares requirements that obviously provide a sufficient condition for polynomial nonnegativity.

Some relatively recent applications that sum of squares relaxations have found span areas as diverse as control theory [33], quantum computation [17], polynomial games [35], combinatorial optimization [19], and many others.

1.2. Convexity and sos-convexity. Aside from nonnegativity, convexity is another fundamental property of polynomials that is of both theoretical and practical significance. Perhaps most notably, presence of convexity in an optimization problem often leads to tractability of finding global optimal solutions. Consider, for example, the problem of finding the unconstrained global minimum of a polynomial. This is an NP-hard problem in general [32], but if we know a priori that the polynomial to be minimized is convex, then every local minimum is global, and even simple gradient descent methods can find a global minimum. There are other scenarios where one would like to decide convexity of polynomials. For example, it turns out that the $d$th root of a degree $d$ polynomial is a norm if and only if the polynomial is homogeneous, positive definite, and convex [42]. Therefore, if we can certify that a homogenous polynomial is convex and definite, then we can use it to define a norm, which is useful in many applications. In many other practical settings, we might want to parameterize a family of convex polynomials that have certain properties, e.g., that serve as a convex envelope for a nonconvex function, approximate a more complicated function, or fit some data points with minimum error. In the field of robust control, for example, it is common to use convex Lyapunov functions to prove stability of uncertain dynamical systems described by difference inclusions. Therefore, the ability to efficiently search over convex polynomials would lead to algorithmic ways of constructing such Lyapunov functions.

The question of determining the computational complexity of deciding convexity of polynomials appeared in 1992 on a list of seven open problems in complexity theory for numerical optimization [31]. In a recent joint work with Olshevsky and Tsitsiklis, we have shown that the problem is strongly NP-hard even for polynomials of degree four [2]. If testing membership in the set of convex polynomials is hard, searching or optimizing over them is obviously also hard. This result, like any other hardness result, stresses the need for good approximation algorithms that can deal with many instances of the problem efficiently.

The focus of this work is on an algebraic notion known as sos-convexity (introduced formally by Helton and Nie in [20]), which is a sufficient condition for convexity of polynomials based on a sum of squares decomposition of the Hessian matrix; see Definition 2.4. As we will briefly review in section 2, the problem of deciding if a given polynomial is sos-convex amounts to solving a single semidefinite program.

Besides its computational implications, sos-convexity is an appealing concept since it bridges the geometric and algebraic aspects of convexity. Indeed, while the usual definition of convexity is concerned only with the geometry of the epigraph, in sos-convexity this geometric property (or the nonnegativity of the Hessian) must be certified through a "simple" algebraic identity, namely, the sum of squares factorization of the Hessian. The original motivation of Helton and Nie for defining
sos-convexity was in relation to the question of semidefinite representability of convex sets [20]. But this notion has already appeared in the literature in a number of other settings [24], [25], [28], [11]. In particular, there has been much recent interest in the role of convexity in semialgebraic geometry [24], [8], [15], [26] and sos-convexity is a recurrent figure in this line of research.

1.3. Contributions and organization of the paper. The main contribution of this work is to establish the counterpart of Hilbert’s characterization of the gap between nonnegativity and sum of squares for the notions of convexity and sos-convexity. We start by presenting some background material in section 2. In section 3, we prove an algebraic analogue of a classical result in convex analysis, which provides three equivalent characterizations for sos-convexity (Theorem 3.1). This result substantiates the fact that sos-convexity is the right sos relaxation for convexity. In section 4, we present some examples of convex polynomials that are not sos-convex. In section 5, we provide the characterization of the gap between convexity and sos-convexity (Theorems 5.1 and 5.2). Subsection 5.1 includes the proofs of the cases where convexity and sos-convexity are equivalent and subsection 5.2 includes the proofs of the cases where they are not. In particular, Theorems 5.8 and 5.9 present explicit examples of convex but not sos-convex polynomials that have dimension and degree as low as possible, and Theorem 5.10 provides a general construction for producing such polynomials in higher degrees. Some concluding remarks and an open problem are presented in section 6.

2. Preliminaries.

2.1. Background on nonnegativity and sum of squares. A (multivariate) polynomial \( p := p(x) \) in variables \( x := (x_1, \ldots, x_n)^T \) is a function from \( \mathbb{R}^n \) to \( \mathbb{R} \) that is a finite linear combination of monomials:

\[
p(x) = \sum_{\alpha} c_{\alpha} x^\alpha = \sum_{(\alpha_1, \ldots, \alpha_n)} c_{\alpha_1, \ldots, \alpha_n} x_1^{\alpha_1} \cdots x_n^{\alpha_n},
\]

where the sum is over \( n \)-tuples of nonnegative integers \( \alpha := (\alpha_1, \ldots, \alpha_n) \). We will be concerned throughout with polynomials with real coefficients, i.e., we will have \( c_{\alpha} \in \mathbb{R} \). The ring of polynomials in \( n \) variables with real coefficients is denoted by \( \mathbb{R}[x] \). The degree of a monomial \( x^\alpha \) is equal to \( \alpha_1 + \cdots + \alpha_n \). The degree of a polynomial \( p \in \mathbb{R}[x] \) is defined to be the highest degree of its component monomials. A polynomial \( p \) is said to be nonnegative or positive semidefinite (psd) if \( p(x) \geq 0 \) for all \( x \in \mathbb{R}^n \). Clearly, a necessary condition for a polynomial to be psd is for its degree to be even. We say that \( p \) is an sum of squares (sos), if there exist polynomials \( q_1, \ldots, q_m \) such that \( p = \sum_{i=1}^m q_i^2 \). We denote the set of psd (resp., sos) polynomials in \( n \) variables and degree \( d \) by \( \check{P}_{n,d} \) (resp., \( \check{\Sigma}_{n,d} \)). Any sos polynomial is clearly psd, so we have \( \check{\Sigma}_{n,d} \subseteq \check{P}_{n,d} \).

A homogeneous polynomial (or a form) is a polynomial where all the monomials have the same degree. A form \( p \) of degree \( d \) is a homogeneous function of degree \( d \) since it satisfies \( p(\lambda x) = \lambda^d p(x) \) for any scalar \( \lambda \in \mathbb{R} \). We say that a form \( p \) is positive definite if \( p(x) > 0 \) for all \( x \neq 0 \) in \( \mathbb{R}^n \). Following standard notation, we denote the set of psd (resp., sos) homogeneous polynomials in \( n \) variables and degree \( d \) by \( P_{n,d} \) (resp., \( \Sigma_{n,d} \)). Once again, we have the obvious inclusion \( \Sigma_{n,d} \subseteq P_{n,d} \). All four sets \( \Sigma_{n,d}, P_{n,d}, \check{\Sigma}_{n,d}, \check{P}_{n,d} \) are closed convex cones. The closedness of the sum of squares cone may not be so obvious. This fact was first proved by Robinson [43]. We will make crucial use of it in the proof of Theorem 3.1 in the next section.
Any form of degree \( d \) in \( n \) variables can be “dehomogenized” into a polynomial of degree \( \leq d \) in \( n-1 \) variables by setting \( x_n = 1 \). Conversely, any polynomial \( p \) of degree \( d \) in \( n \) variables can be “homogenized” into a form \( p_h \) of degree \( d \) in \( n+1 \) variables by adding a new variable \( y \) and letting \( p_h(x_1, \ldots, x_n, y) := y^d p(x_1/y, \ldots, x_n/y) \). The properties of being psd and sos are preserved under homogenization and dehomogenization [40].

A very natural and fundamental question that as we mentioned earlier was answered by Hilbert is to understand for what dimensions and degrees nonnegative polynomials (or forms) can always be represented as sums of squares, i.e., for what values of \( n \) and \( d \) we have \( \Sigma_{n,d} = P_{n,d} \) or \( \Sigma_{n,d} = P_{n,d} \). Note that because of the argument in the last paragraph, we have \( \Sigma_{n,d} = P_{n,d} \) if and only if \( \Sigma_{n+1,d} = P_{n+1,d} \). Hence, it is enough to answer the question just for polynomials or just for forms.

**Theorem 2.1 (Hilbert [22]).** \( \Sigma_{n,d} = P_{n,d} \) if and only if \( n = 1 \) or \( d = 2 \) or \( (n, d) = (2, 3) \). Equivalently, \( \Sigma_{n,d} = P_{n,d} \) if and only if \( n = 2 \) or \( d = 2 \) or \( (n, d) = (3, 4) \).

The proofs of \( \Sigma_{2,4} = \tilde{P}_{2,4} \) (or equivalently \( \Sigma_{3,4} = P_{3,4} \)) is more involved. We refer the interested reader to [37], [36], [13], and references in [40] for some modern expositions and alternative proofs of this result. Hilbert’s other main contribution was to show that these are the only cases where nonnegativity and sum of squares are equivalent by giving a nonconstructive proof of existence of polynomials in \( \tilde{P}_{2,6} \setminus \Sigma_{2,6} \) and \( \tilde{P}_{3,4} \setminus \Sigma_{3,4} \) (or equivalently forms in \( P_{3,6} \setminus \Sigma_{3,6} \) and \( P_{4,4} \setminus \Sigma_{4,4} \)). From this, it follows with simple arguments that in all higher dimensions and degrees there must also be psd but not sos polynomials; see [40]. Explicit examples of such polynomials appeared in the 1960s starting from the celebrated Motzkin form [29],

(2.1) \[
M(x_1, x_2, x_3) = x_1^2x_2^2 + x_1^2x_3^2 - 3x_1^2x_2x_3 + x_3^6,
\]

which belongs to \( P_{3,6} \setminus \Sigma_{3,6} \), and continuing a few years later with the Robinson form [43],

(2.2) \[
R(x_1, x_2, x_3, x_4) = x_1^2(x_1 - x_4)^2 + x_2^2(x_2 - x_4)^2 + x_3^2(x_3 - x_4)^2 \\
+ 2x_1x_2x_3(x_1 + x_2 + x_3 - 2x_4),
\]

which belongs to \( P_{4,4} \setminus \Sigma_{4,4} \).

Several other constructions of psd polynomials that are not sos have appeared in the literature since. An excellent survey is [40]. See also [41] and [9].

### 2.2. Connection to semidefinite programming and matrix generalizations

As we remarked before, what makes sum of squares an appealing concept from a computational viewpoint is its relation to semidefinite programming. It is well-known (see, e.g., [33], [34]) that a polynomial \( p \) in \( n \) variables and of even degree \( d \) is an sum of squares if and only if there exists a positive semidefinite matrix \( Q \) (often called the Gram matrix) such that

\[
p(x) = z^T Q z,
\]

where \( z \) is the vector of monomials of degree up to \( d/2 \)

(2.3) \[
z = [1, x_1, x_2, \ldots, x_n, x_1x_2, \ldots, x_n^{d/2}].
\]

The set of all such matrices \( Q \) is the feasible set of a semidefinite program. For fixed \( d \), the size of this semidefinite program is polynomial in \( n \). Semidefinite programs can be
solved with arbitrary accuracy in polynomial time. There are several implementations of semidefinite programming solvers, based on interior point algorithms among others, that are very efficient in practice and widely used; see [49] and references therein.

The notions of positive semidefiniteness and sum of squares of scalar polynomials can be naturally extended to polynomial matrices, i.e., matrices with entries in \( \mathbb{R}[x] \). We say that a symmetric polynomial matrix \( U(x) \in \mathbb{R}[x]^{m \times m} \) is positive semidefinite if \( U(x) \) is positive semidefinite in the matrix sense for all \( x \in \mathbb{R}^n \), i.e., if \( U(x) \) has nonnegative eigenvalues for all \( x \in \mathbb{R}^n \). It is straightforward to see that this condition holds if and only if the scalar polynomial \( y^T U(x) y \) in \( m+n \) variables \( [x; y] \) is psd. A homogeneous polynomial matrix \( U(x) \) is said to be positive definite if it is positive definite in the matrix sense, i.e., has positive eigenvalues, for all \( x \neq 0 \) in \( \mathbb{R}^n \). The definition of an sos-matrix is as follows [23], [18], [45].

**Definition 2.2.** A symmetric polynomial matrix \( U(x) \in \mathbb{R}[x]^{m \times m}, x \in \mathbb{R}^n \), is an sos-matrix if there exists a polynomial matrix \( V(x) \in \mathbb{R}[x]^{s \times s} \) for some \( s \in \mathbb{N} \) such that \( P(x) = V^T(x)V(x) \).

It turns out that a polynomial matrix \( U(x) \in \mathbb{R}[x]^{m \times m}, x \in \mathbb{R}^n \), is an sos-matrix if and only if the scalar polynomial \( y^T U(x) y \) is an sum of squares in \( \mathbb{R}[x; y] \); see [23]. This is a useful fact because in particular it gives us an easy way of checking whether a polynomial matrix is an sos-matrix by solving a semidefinite program. Once again, it is obvious that being an sos-matrix is a sufficient condition for a polynomial matrix to be positive semidefinite.

### 2.3. Background on convexity and sos-convexity.

A polynomial \( p \) is (globally) convex if for all \( x \) and \( y \) in \( \mathbb{R}^n \) and all \( \lambda \in [0, 1] \), we have

\[
(2.4) \quad p(\lambda x + (1 - \lambda)y) \leq \lambda p(x) + (1 - \lambda)p(y).
\]

Since polynomials are continuous functions, the inequality in (2.4) holds if and only if it holds for a fixed value of \( \lambda \in (0, 1) \), say, \( \lambda = \frac{1}{2} \). In other words, \( p \) is convex if and only if

\[
(2.5) \quad p\left(\frac{1}{2}x + \frac{1}{2}y\right) \leq \frac{1}{2}p(x) + \frac{1}{2}p(y)
\]

for all \( x \) and \( y \); see, e.g., [44, p. 71]. Except for the trivial case of linear polynomials, an odd degree polynomial is clearly never convex.

For the sake of direct comparison with a result that we derive in the next section (Theorem 3.1), we recall next a classical result from convex analysis on the first and second order characterization of convexity. The proof can be found in many convex optimization textbooks, e.g., [10, p. 70]. The theorem is of course true for any twice differentiable function, but for our purposes we state it for polynomials.

**Theorem 2.3.** Let \( p := p(x) \) be a polynomial. Let \( \nabla p := \nabla p(x) \) denote its gradient and let \( H := H(x) \) be its Hessian, i.e., the \( n \times n \) symmetric matrix of second derivatives. Then the following are equivalent:

(a) \( p\left(\frac{1}{2}x + \frac{1}{2}y\right) \leq \frac{1}{2}p(x) + \frac{1}{2}p(y) \) for all \( x, y \in \mathbb{R}^n \) (i.e., \( p \) is convex).

(b) \( p(y) \geq p(x) + \nabla p(x)^T (y - x) \) for all \( x, y \in \mathbb{R}^n \) (i.e., \( p \) lies above the support hyperplane at every point).

(c) \( y^T H(x) y \geq 0 \) for all \( x, y \in \mathbb{R}^n \) (i.e., \( H(x) \) is a psd polynomial matrix).

Helton and Nie proposed in [20] the notion of sos-convexity as an sos relaxation for the second order characterization of convexity (condition (c) above).

**Definition 2.4.** A polynomial \( p \) is sos-convex if its Hessian \( H := H(x) \) is an sos-matrix.
With what we have discussed so far, it should be clear that sos-convexity is a sufficient condition for convexity of polynomials and can be checked with semidefinite programming. In the next section, we will show some other natural sos relaxations for polynomial convexity, which will turn out to be equivalent to sos-convexity.

We end this section by introducing some final notation: \( \tilde{C}_{n,d} \) and \( \Sigma_{C_{n,d}} \) will respectively denote the set of convex and sos-convex polynomials in \( n \) variables and degree \( d \); \( C_{n,d} \) and \( \Sigma_{C_{n,d}} \) will respectively denote set of convex and sos-convex homogeneous polynomials in \( n \) variables and degree \( d \). Again, these four sets are closed convex cones and we have the obvious inclusions \( \Sigma_{C_{n,d}} \subseteq \tilde{C}_{n,d} \) and \( \Sigma_{C_{n,d}} \subseteq C_{n,d} \).

3. Equivalent algebraic relaxations for convexity of polynomials. An obvious way to formulate alternative sos relaxations for convexity of polynomials is to replace every inequality in Theorem 2.3 with its sos version. In this section we examine how these relaxations relate to each other. We also comment on the size of the resulting semidefinite programs.

Our result below can be thought of as an algebraic analogue of Theorem 2.3.

**Theorem 3.1.** Let \( p := p(x) \) be a polynomial of degree \( d \) in \( n \) variables with its gradient and Hessian denoted respectively by \( \nabla p := \nabla p(x) \) and \( H := H(x) \). Let \( g_\lambda \), \( g_{\nabla} \), and \( g_{\nabla^2} \) be defined as

\[
\begin{align*}
g_\lambda(x,y) &= (1 - \lambda)p(x) + \lambda p(y) - p((1 - \lambda)x + \lambda y), \\
g_{\nabla}(x,y) &= p(y) - p(x) - \nabla p(x)^T (y - x), \\
g_{\nabla^2}(x,y) &= y^T H(x)y.
\end{align*}
\]

Then the following are equivalent:

(a) \( g_{1/2}(x,y) \) is sos.\(^1\)

(b) \( g_{\nabla}(x,y) \) is sos.

(c) \( g_{\nabla^2}(x,y) \) is sos (i.e., \( H(x) \) is an sos-matrix).

**Proof.** (a)\( \Rightarrow \) (b). Assume \( g_{1/2} \) is sos. We start by proving that \( g_{1/2} \) will also be sos for any integer \( k \geq 2 \). A little bit of straightforward algebra yields the relation

\[
g_{1/2^k}(x,y) = \frac{1}{2} g_{1/2}(x,y) + g_{1/2}
\left(x, \frac{x^k - 1}{2^k - 1}x + \frac{1}{2^k}y\right).
\]

The second term on the right-hand side of (3.2) is always sos because \( g_{1/2} \) is sos. Hence, this relation shows that for any \( k \), if \( g_{1/2} \) is sos, then so is \( g_{1/2^k} \). Since for \( k = 1 \), both terms on the right-hand side of (3.2) are sos by assumption, induction immediately gives that \( g_{1/2} \) is sos for all \( k \).

Now, let us rewrite \( g_\lambda \) as

\[
g_\lambda(x,y) = p(x) + \lambda (p(y) - p(x)) - p(x + \lambda(y - x)).
\]

We have

\[
g_\lambda(x,y) = \frac{p(y) - p(x) - p(x + \lambda(y - x)) - p(x)}{\lambda}.
\]

Next, we take the limit of both sides of (3.3) by letting \( \lambda = \frac{1}{x^k} \to 0 \) as \( k \to \infty \). Because \( p \) is differentiable, the right-hand side of (3.3) will converge to \( g_\nabla \). On the other hand, our preceding argument implies that \( g_{1/2} \) is an sos polynomial (of degree

\^1The constant \( \frac{1}{2} \) in \( g_{1/2}(x,y) \) of condition (a) is arbitrary and chosen for convenience. One can show that \( g_{1/2} \) being sos implies that \( g_\lambda \) is sos for any fixed \( \lambda \in (0, 1) \). Conversely, if \( g_\lambda \) is sos for some \( \lambda \in (0, 1) \), then \( g_{1/2} \) is sos. The proofs are similar to the proof of (a)\( \Rightarrow \) (b).
Since \( y \) is an sos polynomial of degree (3.5) and hence \( g_\nu \) is sos. It is easy to check that
\[
g_\nu^T(x, y) = \frac{1}{2} g_\nu \left( \frac{1}{2} x + \frac{1}{2} y, x \right) + \frac{1}{2} g_\nu \left( \frac{1}{2} x + \frac{1}{2} y, y \right),
\]
and hence \( g_\nu^T \) is sos.

(b) \( \Rightarrow \) (a). Assume \( g_\nu^T \) is sos. It is easy to check that
\[
p(y) = p(x) + \nabla^T p(x)(y - x)
+ \frac{1}{2} (y - x)^T H(x)(y - x) + o(||y - x||^2).
\]
After rearranging terms, letting \( y = x + \epsilon z \) (for \( \epsilon > 0 \)), and dividing both sides by \( \epsilon^2 \) we get
\[
(p(x + \epsilon z) - p(x))/\epsilon^2 - \nabla^T p(x)z/\epsilon = \frac{1}{2} z^T H(x)z + 1/\epsilon^2 o(\epsilon^2 ||z||^2).
\]
The left-hand side of (3.4) is \( g_\nu^T(x, x + \epsilon z)/\epsilon^2 \) and therefore for any fixed \( \epsilon > 0 \), it is an sos polynomial by assumption. As we take \( \epsilon \rightarrow 0 \), by closedness of the sos cone, the left-hand side of (3.4) converges to an sos polynomial. On the other hand, as the limit is taken, the term \( 1/\epsilon^2 o(\epsilon^2 ||z||^2) \) vanishes and hence we have that \( z^T H(x)z \) must be sos.

(c) \( \Rightarrow \) (b). Following the strategy of the proof of the classical case in [48, p. 165], we start by writing the Taylor expansion of \( p_\nu \) around \( x \) with the integral form of the remainder:
\[
(p(y) - p(x))/\epsilon^2 - \nabla^T p(x)(y - x) + \int_0^1 (1 - t)(y - x)^T H(x + t(y - x))(y - x)dt.
\]
Since \( y^T H(x) y \) is sos by assumption, for any \( t \in [0, 1] \) the integrand
\[
(1 - t)(y - x)^T H(x + t(y - x))(y - x)
\]
is an sos polynomial of degree \( d \) in \( x \) and \( y \). From (3.5) we have
\[
g_\nu^T = \int_0^1 (1 - t)(y - x)^T H(x + t(y - x))(y - x)dt.
\]
It then follows that \( g_\nu^T \) is sos because integrals of sos polynomials, if they exist, are sos. To see the latter fact, note that we can write the integral as a limit of a sequence of Riemann sums by discretizing the interval \([0, 1]\) over which we are integrating. Since every finite Riemann sum is an sos polynomial of degree \( d \), and since the sos cone is closed, it follows that the limit of the sequence must be sos.

We conclude that conditions (a), (b), and (c) are equivalent sufficient conditions for convexity of polynomials and can each be checked with a semidefinite program as explained in subsection 2.2. It is easy to see that all three polynomials \( g_\nu^T(x, y) \), \( g_\nu(x, y) \), and \( g_{\nu^2}(x, y) \) are polynomials in \( 2n \) variables and of degree \( d \). (Note that each differentiation reduces the degree by one.) Each of these polynomials has a specific structure that can be exploited for formulating smaller semidefinite programs. For example, the symmetries \( g_\nu^T(x, y) = g_\nu^T(y, x) \) and \( g_{\nu^2}(x, -y) = g_{\nu^2}(x, y) \) can be taken advantage of via symmetry reduction techniques developed in [18].
The issue of symmetry reduction aside, we would like to point out that formulation (c) (which was the original definition of sos-convexity) can be significantly more efficient than the other two conditions. The reason is that the polynomial \( g_{\mathcal{T},2}(x,y) \) is always quadratic and homogeneous in \( y \) and of degree \( d - 2 \) in \( x \). This makes \( g_{\mathcal{T},2}(x,y) \) much more sparse than \( g_{\mathcal{T}}(x,y) \) and \( g_{\mathcal{T},2}(x,y) \), which have degree \( d \) both in \( x \) and in \( y \). Furthermore, because of the special bipartite structure of \( y^T H(x) y \), only monomials of the form \( x^i y_j \) (i.e., linear in \( y \)) will appear in the vector of monomials (2.3). This in turn reduces the size of the Gram matrix and hence the size of the semidefinite program. It is perhaps not too surprising that the characterization of convexity based on the Hessian matrix is a more efficient condition to check. After all, at a given point \( x \), the property of having nonnegative curvature in every direction is a local condition, whereas characterizations (a) and (b) both involve global conditions.

Remark 3.1. There has been yet another proposal for an sos relaxation for convexity of polynomials in [11]. However, we have shown in [4] that the condition in [11] is at least as conservative as the three conditions in Theorem 3.1 and also significantly more expensive to check.

Remark 3.2. Just like convexity, the property of sos-convexity is preserved under restrictions to affine subspaces. This is perhaps most directly seen through characterization (a) of sos-convexity in Theorem 3.1 by also noting that sum of squares is preserved under restrictions to affine subspaces. This is perhaps most directly seen through characterization (a) of sos-convexity in Theorem 3.1 by also noting that sum of squares is preserved under restrictions. Unlike convexity, however, if a polynomial is sos-convex on every line (or even on every proper affine subspace), this does not imply that the polynomial is sos-convex.

As an application of Theorem 3.1, we use our new characterization of sos-convexity to give a short proof of an interesting lemma of Helton and Nie.

**Lemma 3.2** (Helton and Nie [20, Lemma 8]). Every sos-convex form is sos.

**Proof.** Let \( p \) be an sos-convex form of degree \( d \). We know from Theorem 3.1 that sos-convexity of \( p \) is equivalent to the polynomial \( g_{\frac{1}{2}}(x,y) = \frac{1}{2}p(x) + \frac{1}{2}p(y) - p(\frac{1}{2}x + \frac{1}{2}y) \) being sos. But since sos is preserved under restrictions and \( p(0) = 0 \), this implies that
\[
g_{\frac{1}{2}}(x,0) = \frac{1}{2}p(x) - p(\frac{1}{2}x) = 0
\]
is sos. \( \square \)

Note that the same argument also shows that convex forms are psd.

4. Some constructions of convex but not sos-convex polynomials. It is natural to ask whether sos-convexity is not only a sufficient condition for convexity of polynomials but also a necessary one. In other words, could it be the case that if the Hessian of a polynomial is positive semidefinite, then it must factor? To give a negative answer to this question, one has to prove existence of a convex polynomial that is not sos-convex, i.e., a polynomial \( p \) for which one (and hence all) of the three polynomials \( g_{\frac{1}{2}}, g_T, \) and \( g_{\mathcal{T},2} \) in (3.1) are psd but not sos. Note that existence of psd but not sos polynomials does not imply existence of convex but not sos-convex polynomials on its own. The reason is that the polynomials \( g_{\frac{1}{2}}, g_T, \) and \( g_{\mathcal{T},2} \) all possess a very special structure.\(^2\) For example, \( y^T H(x) y \) has the structure of being quadratic in \( y \) and a Hessian in \( x \). (Not every polynomial matrix is a valid Hessian.) The

\(^2\)There are many situations where requiring a specific structure on polynomials makes psd equivalent to sos. As an example, we know that there are forms in \( P_{4,4} \setminus \Sigma_{4,4} \). However, if we require the forms to have only even monomials, then all such nonnegative forms in four variables and degree 4 are sos [16].
which such polynomials can exist. This is achieved in the next theorem.

Now that we know there exist convex polynomials that are not sos-convex, our final goal is to give a complete characterization of the degrees and dimensions in which this is possible.

In an earlier paper, we presented the first example of a convex but not sos-convex polynomial [5], [3]:

\begin{equation}
\begin{aligned}
p(x_1, x_2, x_3) &= 32x_1^4 + 118x_1^2 x_2^2 + 40x_1^2 x_3^2 + 25x_1^4 x_2^4 - 43x_1^4 x_2^2 x_3^2 - 35x_1^4 x_3^4 + 3x_1^4 x_2^4 x_3^2 \\
&\quad - 16x_1^4 x_2^2 x_3^4 + 24x_1^2 x_3^6 + 16x_3^8 + 44x_2^6 x_3^2 + 70x_1^4 x_3^4 + 60x_2^6 x_3^2 + 30x_3^8.
\end{aligned}
\end{equation}

As we will see later in this paper, this form which lives in $C_{3,8} \setminus \Sigma C_{3,8}$ turns out to be an example in the smallest possible number of variables but not in the smallest degree. We present another example of a convex but not sos-convex form that has not been previously in print. The example is in $C_{6,4} \setminus \Sigma C_{6,4}$ and by contrast to the previous example, it will turn out to be minimal in the degree but not in the number of variables. What is nice about this example is that unlike the other examples in this paper it has not been derived with the assistance of a computer and semidefinite programming:

\begin{equation}
\begin{aligned}
q(x_1, \ldots, x_6) &= x_1^4 + x_2^4 + x_3^4 + x_4^4 + x_5^4 + x_6^4 \\
&\quad + 2(x_1^2 x_2^2 + x_1^2 x_3^2 + x_2^2 x_3^2 + x_4^2 x_5^2 + x_4^2 x_6^2 + x_5^2 x_6^2) \\
&\quad + \frac{1}{2}(x_1^2 x_4^2 + x_2^2 x_5^2 + x_3^2 x_6^2) + x_1^2 x_6^2 + x_2^2 x_4^2 + x_3^2 x_5^2 \\
&\quad - (x_1 x_2 x_4 x_5 + x_1 x_3 x_4 x_6 + x_2 x_3 x_5 x_6).
\end{aligned}
\end{equation}

The proof that this polynomial is convex but not sos-convex can be extracted from [2, Theorems 2.3 and 2.5]. There, a general procedure is described for producing convex but not sos-convex quartic forms from any example of a psd but not sos biquadratic form. The biquadratic form that has led to the form above is that of Choi in [14].

Also note that the example in (4.2) shows that convex forms that possess strong symmetry properties can still fail to be sos-convex. The symmetries in this form are inherited from the rich symmetry structure of the biquadratic form of Choi (see [18]). In general, symmetries are of interest in the study of positive semidefinite and sums of squares polynomials because the gap between psd and sos can often behave very differently depending on the symmetry properties; see, e.g., [7].

5. Characterization of the gap between convexity and sos-convexity.

Now that we know there exist convex polynomials that are not sos-convex, our final main goal is to give a complete characterization of the degrees and dimensions in which such polynomials can exist. This is achieved in the next theorem.

**Theorem 5.1.** $\Sigma C_{n,d} = \hat{C}_{n,d}$ if and only if $n = 1$ or $d = 2$ or $(n, d) = (2, 4)$.

We would also like to have such a characterization for homogeneous polynomials. Although convexity is a property that is in some sense more meaningful for nonhomogeneous polynomials than for forms, one motivation for studying convexity of forms is in their relation to norms [42]. Also, in view of the fact that we have a characterization of the gap between nonnegativity and sos both for polynomials and for forms,

---

3Assuming $P \neq \text{NP}$, and given the NP-hardness of deciding polynomial convexity [2], one would expect to see convex polynomials that are not sos-convex. However, our first example in [5] appeared before the proof of NP-hardness [2]. Moreover, from complexity considerations, even assuming $P \neq \text{NP}$, one cannot conclude existence of convex but not sos-convex polynomials for any finite value of the number of variables $n$.

it is very natural to inquire for the same result for convexity and sos-convexity. The next theorem presents this characterization for forms.

**Theorem 5.2.** \( \Sigma C_{n,d} = C_{n,d} \) if and only if \( n = 2 \) or \( d = 2 \) or \((n, d) = (3, 4)\).

The result \( \Sigma C_{3,4} = C_{3,4} \) of this theorem is joint work with Blekherman and is to be presented in full detail in [1]. The remainder of this paper is solely devoted to the proofs of Theorems 5.1 and 5.2 except for the case \((n, d) = (3, 4)\). Before we present these proofs, we shall make two important remarks.

**Remark 5.1** (difficulty with homogenization and dehomogenization). Recall from subsection 2.1 and Theorem 2.1 that characterizing the gap between nonnegativity and sum of squares for polynomials is equivalent to accomplishing this task for forms. Unfortunately, the situation is more complicated for convexity and sos-convexity and this is why we are presenting Theorems 5.1 and 5.2 as separate theorems. The difficulty arises from the fact that unlike nonnegativity and sum of squares, convexity and sos-convexity are not always preserved under homogenization. (Or equivalently, the properties of being not convex and not sos-convex are not preserved under dehomogenization.) In fact, any convex polynomial that is not psd will no longer be convex after homogenization. This is because convex forms are psd but the homogenization of a non-psd polynomial is a non-psd form. Even if a convex polynomial is psd, its homogenization may not be convex. For example, the univariate polynomial \( 10x_1^4 - 5x_1 + 2 \) is convex and psd, but its homogenization \( 10x_1^4 - 5x_1x_2^2 + 2x_2^4 \) is not convex. To observe the same phenomenon for sos-convexity, consider the trivariate form \( p \) in (4.1) which is convex but not sos-convex and define \( \tilde{p}(x_2, x_3) = p(1, x_2, x_3) \). Then, one can check that \( \tilde{p} \) is sos-convex (i.e., its \( 2 \times 2 \) Hessian factors) even though its homogenization which is \( p \) is not sos-convex [5].

**Remark 5.2** (resemblance to the result of Hilbert). The reader may have noticed from the statements of Theorem 2.1 and Theorems 5.1 and 5.2 that the cases where convex polynomials (forms) are sos-convex are exactly the same cases where nonnegative polynomials are sos! We shall emphasize that as far as we can tell, our results do not follow (except in the simplest cases) from Hilbert’s result stated in Theorem 2.1. Note that the question of convexity or sos-convexity of a polynomial \( p(x) \) in \( n \) variables and degree \( d \) is about the polynomials \( g_{4,2}(x, y), g_{4,2}(x, y), \) or \( g_{3,4}(x, y) \) defined in (3.1) being psd or sos. Even though these polynomials still have degree \( d \), it is important to keep in mind that they are polynomials in \( 2n \) variables. Therefore, there is no direct correspondence with the characterization of Hilbert. To make this more explicit, let us consider, for example, one particular claim of Theorem 5.2: \( \Sigma C_{2,4} = C_{2,4} \). For a form \( p \) in two variables and degree 4, the polynomials \( g_{2,4}, g_{3,4}, \) and \( g_{2,4} \) will be forms in four variables and degree 4. We know from Hilbert’s result that in this situation psd but not sos forms do in fact exist. However, for the forms in four variables and degree 4 that have the special structure of \( g_{2,4}, g_{3,4}, \) or \( g_{2,4} \), psd turns out to be equivalent to sos.

The proofs of Theorems 5.1 and 5.2 are broken into the next two subsections. In subsection 5.1, we provide the proofs for the cases where convexity and sos-convexity are equivalent. Then in subsection 5.2, we prove that in all other cases there exist convex polynomials that are not sos-convex.

**5.1. Proofs of Theorems 5.1 and 5.2: Cases where \( \Sigma C_{n,d} = \tilde{C}_{n,d}, \Sigma C_{n,d} = C_{n,d} \).** When proving equivalence of convexity and sos-convexity, it turns...
out to be more convenient to work with the second order characterization of sos-convexity, i.e., with the form \( q_{\mathcal{T}_2}(x, y) = y^T H(x) y \) in (3.1). The reason for this is that this form is always quadratic in \( y \), and this allows us to make use of the following key theorem, henceforth referred to as the "biform theorem."

**Theorem 5.3** (e.g., [12]). Let \( f := f(u_1, u_2, v_1, \ldots, v_m) \) be a form in the variables \( u := (u_1, u_2)^T \) and \( v := (v_1, \ldots, v_m)^T \) that is a quadratic form in \( v \) for fixed \( u \) and a form (of any degree) in \( u \) for fixed \( v \). Then \( f \) is psd if and only if it is sos.\(^5\)

The biform theorem has been proved independently by several authors. See [12] and [6] for more background on this theorem and in particular [12, section 7] for an elegant proof and some refinements. We now proceed with our proofs, which will follow in a rather straightforward manner from the biform theorem.

**Theorem 5.4.** \( \Sigma C_{1,d} = \tilde{C}_{1,d} \) for all \( d \). \( \Sigma C_{2,d} = C_{2,d} \) for all \( d \).

*Proof.* For a univariate polynomial, convexity means that the second derivative, which is another univariate polynomial, is psd. Since \( \Sigma_{1,d} = \tilde{P}_{1,d} \), the second derivative must be sos. Therefore, \( \Sigma C_{1,d} = \tilde{C}_{1,d} \). To prove \( \Sigma C_{2,d} = C_{2,d} \), suppose we have a convex bivariate form \( p \) of degree \( d \) in variables \( x := (x_1, x_2) \). The Hessian \( H := H(x) \) of \( p \) is a \( 2 \times 2 \) matrix whose entries are forms of degree \( d - 2 \). If we let \( y := (y_1, y_2)^T \), convexity of \( p \) implies that the form \( y^T H(x) y \) is psd. Since \( y^T H(x) y \) meets the requirements of the biform theorem above with \((u_1, u_2) = (x_1, x_2) \) and \((v_1, v_2) = (y_1, y_2) \), it follows that \( y^T H(x) y \) is sos. Hence, \( p \) is sos-convex. \( \Box \)

**Theorem 5.5.** \( \Sigma C_{n,2} = C_{n,2} \) for all \( n \). \( \Sigma C_{n,2} = C_{n,2} \) for all \( n \).

*Proof.* Let \( x := (x_1, \ldots, x_n)^T \) and \( y := (y_1, \ldots, y_n)^T \). Let \( p(x) = \frac{1}{2} x^T Q x + b^T x + c \) be a quadratic polynomial. The Hessian of \( p \) in this case is the constant symmetric matrix \( Q \). Convexity of \( p \) implies that \( y^T Q y \) is psd. But since \( \Sigma_{n,2} = P_{n,2} \), \( y^T Q y \) must be sos. Hence, \( p \) is sos-convex. The proof of \( \Sigma C_{n,2} = C_{n,2} \) is identical. \( \Box \)

**Theorem 5.6.** \( \Sigma C_{2,4} = \tilde{C}_{2,4} \).

*Proof.* Let \( p(x) := p(x_1, x_2) \) be a convex bivariate quartic polynomial. Let \( H := H(x) \) denote the Hessian of \( p \) and let \( y := (y_1, y_2)^T \). Note that \( H(x) \) is a \( 2 \times 2 \) matrix whose entries are (not necessarily homogeneous) quadratic polynomials. Since \( p \) is convex, \( y^T H(x) y \) is psd. Let \( H(x_1, x_2, x_3) \) be a \( 2 \times 2 \) matrix whose entries are obtained by homogenizing the entries of \( H \). It is easy to see that \( y^T H(x_1, x_2, x_3) y \) is then the form obtained by homogenizing \( y^T H(x) y \) and is therefore psd. Now we can employ the biform theorem (Theorem 5.3) with \((u_1, u_2) = (y_1, y_2) \) and \((v_1, v_2, v_3) = (x_1, x_2, x_3) \) to conclude that \( y^T H(x_1, x_2, x_3) y \) is sos. But upon dehomogenizing by setting \( x_3 = 1 \), we conclude that \( y^T H(x_1, x_2, x_3) y \) is sos. Hence, \( p \) is sos-convex. \( \Box \)

**Theorem 5.7** (Ahmadi, Blekherman, and Parrilo [1]). \( \Sigma C_{3,4} = C_{3,4} \).

Unlike Hilbert’s results \( \Sigma C_{2,4} = P_{2,4} \) and \( \Sigma C_{3,4} = P_{3,4} \) which are equivalent statements and essentially have identical proofs, the proof of \( \Sigma C_{3,4} = C_{3,4} \) is considerably more involved than the proof of \( \Sigma C_{2,4} = \tilde{C}_{2,4} \). Here, we briefly point out why this is the case and refer the reader to [1] for more details.

If \( p(x) := p(x_1, x_2, x_3) \) is a ternary quartic form, its Hessian \( H(x) \) is a \( 3 \times 3 \) matrix whose entries are quadratic forms. In this case, we can no longer apply the biform theorem to the form \( y^T H(x) y \). In fact, the matrix

\[
C(x) = \begin{bmatrix}
x_1^2 + 2x_2^2 & -x_1x_2 & -x_1x_3 \\
-x_1x_2 & x_2^2 + 2x_3^2 & -x_2x_3 \\
-x_1x_3 & -x_2x_3 & x_3^2 + 2x_1^2
\end{bmatrix}
\]

\(^5\)Note that the results \( \Sigma_{2,d} = P_{2,d} \) and \( \Sigma_{n,2} = P_{n,2} \) are both special cases of this theorem.
due to Choi [14] serves as an explicit example of a $3 \times 3$ matrix with quadratic form entries that is positive semidefinite but not an sos-matrix; i.e., $y^T C(x) y$ is psd but not sos. However, the matrix $C(x)$ above is not a valid Hessian, i.e., it cannot be the matrix of the second derivatives of any polynomial. If this were the case, the third partial derivatives would commute. On the other hand, we have in particular

$$\frac{\partial C_{1,1}(x)}{\partial x_3} = 0 \neq -x_3 = \frac{\partial C_{1,3}(x)}{\partial x_1}.$$  

It is rather remarkable that with the additional requirement of being a valid Hessian, the form $y^T H(x) y$ turns out to be psd if and only if it is sos [1].

5.2. Proofs of Theorems 5.1 and 5.2: Cases where $\Sigma C_{n,d} \subset \tilde{C}_{n,d}, \Sigma C_{n,d} \subset C_{n,d}$. The goal of this subsection is to establish that the cases presented in the previous subsection are the only cases where convexity and sos-convexity are equivalent. We will first give explicit examples of convex but not sos-convex polynomials/forms that are “minimal” jointly in the degree and dimension and then present an argument for all dimensions and degrees higher than those of the minimal cases.

5.2.1. Minimal convex but not sos-convex polynomials/forms. The minimal examples of convex but not sos-convex polynomials (resp., forms) turn out to belong to $\tilde{C}_{2,6} \setminus \Sigma C_{2,6}$ and $\tilde{C}_{3,4} \setminus \Sigma C_{3,4}$ (resp., $C_{3,6} \setminus \Sigma C_{3,6}$ and $C_{4,4} \setminus \Sigma C_{4,4}$). Recall from Remark 5.1 that we lack a general argument for going from convex but not sos-convex forms to polynomials or vice versa. Because of this, one would need to present four different polynomials in the sets mentioned above and prove that each polynomial is (i) convex and (ii) not sos-convex. This is a total of eight arguments to make, which is quite cumbersome. However, as we will see in the proofs of Theorems 5.8 and 5.9 below, we have been able to find examples that act “nicely” with respect to particular ways of dehomogenization. This will allow us to reduce the total number of claims we have to prove from eight to four.

The polynomials that we present next have been found with the assistance of a computer and by employing some “tricks” with semidefinite programming. In this process, we have made use of software packages YALMIP [27] and SOSTOOLS [38] and the semidefinite programming solver SeDuMi [47], which we acknowledge here. To make the paper relatively self-contained and to emphasize the fact that using rational sum of squares certificates one can make such computer assisted proofs fully formal, we present the proof of Theorem 5.8 below in the appendix. On the other hand, the proof of Theorem 5.9, which is very similar in style to the proof of Theorem 5.8, is largely omitted to save space. All the proofs are available in electronic form and in their entirety at http://aaa.lids.mit.edu/software or at http://arxiv.org/abs/1111.4587.

**Theorem 5.8.** $\Sigma C_{2,6}$ is a proper subset of $\tilde{C}_{2,6}$. $\Sigma C_{3,6}$ is a proper subset of $C_{3,6}$.

**Proof.** We claim that the form

\begin{equation}
(5.1)
f(x_1, x_2, x_3)
= 77x_1^6 - 155x_1^5x_2 + 445x_1^4x_2^2 + 76x_1^3x_2^3 + 556x_2^2x_3^2 + 68x_1x_2^5 + 240x_2^6 - 9x_1^5x_3
- 1129x_1^4x_2^2x_3 + 62x_1^3x_2^3x_3 + 1206x_1x_2^2x_3^2 - 343x_2^2x_3^2 + 363x_1^4x_3^2 + 773x_1^3x_2x_3^2
\end{equation}
belongs to $C_{3,6} \setminus \Sigma C_{3,6}$ and the polynomial
\begin{equation}
\tilde{f}(x_1, x_2) = f \left( x_1, x_2, 1 - \frac{1}{2} x_2 \right)
\end{equation}
belongs to $\tilde{C}_{2,6} \setminus \Sigma \tilde{C}_{2,6}$. Note that since convexity and sos-convexity are both preserved under restrictions to affine subspaces (recall Remark 3.2), it suffices to show that the form $f$ in (5.1) is convex and the polynomial $\tilde{f}$ in (5.2) is not sos-convex. Let $x := (x_1, x_2, x_3)^T$, $y := (y_1, y_2, y_3, y_4)^T$, $\tilde{x} := (x_1, x_2)^T$, $\tilde{y} := (y_1, y_2)^T$, and denote the Hessian of $f$ and $\tilde{f}$ respectively by $H_f$ and $H_{\tilde{f}}$. In the appendix, we provide rational Gram matrices which prove that the form
\begin{equation}
(x_1^2 + x_2^2) \cdot y^T H_f(x) y
\end{equation}
is sos. This, together with nonnegativity of $x_1^2 + x_2^2$ and continuity of $y^T H_f(x) y$, implies that $y^T H_f(x) y$ is psd. Therefore, $f$ is convex. The proof that $\tilde{f}$ is not sos-convex proceeds by showing that $H_{\tilde{f}}$ is not an sos-matrix via a separation argument. In the appendix, we present a separating hyperplane that leaves the appropriate sos cone on one side and the polynomial
\begin{equation}
\tilde{y}^T H_{\tilde{f}}(\tilde{x}) \tilde{y}
\end{equation}
on the other.

**Theorem 5.9.** $\Sigma C_{3,4}$ is a proper subset of $\tilde{C}_{3,4}$. $\Sigma C_{4,4}$ is a proper subset of $C_{4,4}$.

**Proof.** We claim that the form
\begin{equation}
h(x_1, \ldots, x_9)
= 1671x_1^4 - 4134x_1^2 x_2 - 3332x_1^2 x_3 + 5104x_1^2 x_2 x_3 + 3490x_1^2 x_2^2 - 2203x_1 x_2^2
- 3030x_1 x_2^2 x_3 - 3776x_1 x_2 x_3^2 - 1522 x_1 x_3^3 + 1227 x_2^3 - 595 x_2 x_3^3 + 1859 x_2^2 x_3^2
+ 1146 x_2^2 x_3^2 + 979 x_3^4 + 1195728 x_4^4 - 1932 x_1 x_3^4 - 2296 x_2 x_3^4 - 3144 x_3 x_4^2
\begin{equation}
+ 1465 x_1^2 x_2^2 - 1376 x_1^2 x_4 - 263 x_1 x_2 x_4^2 + 2790 x_2^2 x_3 x_4 + 2121 x_2^2 x_4^2 - 292 x_1 x_2^2 x_4
- 1224 x_3^2 x_4 + 2404 x_1 x_3 x_4^2 + 2727 x_2 x_3 x_4^2 - 2852 x_1 x_3^2 x_4 - 388 x_2 x_3^2 x_4
- 1520 x_3^2 x_4 + 2943 x_1^2 x_3 x_4 + 5053 x_1 x_2 x_3 x_4 + 2552 x_2^2 x_3 x_4 + 3512 x_3^2 x_4
\end{equation}
begins to $C_{4,4} \setminus \Sigma C_{4,4}$ and the polynomial
\begin{equation}
\hat{h}(x_1, x_2, x_3) = h(x_1, x_2, x_3, 1)
\end{equation}
belongs to $\hat{C}_{3,4} \setminus \Sigma \hat{C}_{3,4}$. Once again, it suffices to prove that $h$ is convex and $\hat{h}$ is not sos-convex. Let $x := (x_1, x_2, x_3, x_4)^T$, $y := (y_1, y_2, y_3, y_4)^T$, and denote the Hessian of $h$ and $\hat{h}$ respectively by $H_h$ and $H_{\hat{h}}$. The proof that $h$ is convex is done by showing that the form
\begin{equation}
(x_2^2 + x_3^2 + x_4^2) \cdot y^T H_h(x) y
\end{equation}
is not sos-convex. This, together with nonnegativity of $x_2^2 + x_3^2 + x_4^2$, implies that $x_2^2 + x_3^2 + x_4^2$ is psd, and therefore, $h$ is convex. The proof that $\hat{h}$ is not sos-convex proceeds by showing that $H_{\hat{h}}$ is not an sos-matrix via a separation argument. In the appendix, we present a separating hyperplane that leaves the appropriate sos cone on one side and the polynomial
\begin{equation}
\hat{y}^T H_{\hat{f}}(\hat{x}) \hat{y}
\end{equation}
on the other.

---

\footnote{The polynomial $f(x_1, x_2, 1)$ turns out to be sos-convex and therefore does not do the job. One can of course change coordinates and then in the new coordinates perform the dehomogenization by setting $x_3 = 1$.}
is sos.\(^8\) The proof that \(\tilde{h}\) is not sos-convex is done again by means of a separating hyperplane. \(\Box\)

#### 5.2.2. Convex but not sos-convex polynomials/forms in all higher degrees and dimensions

Given a convex but not sos-convex polynomial (form) in \(n\) variables, it is very easy to argue that such a polynomial (form) must also exist in a larger number of variables. If \(p(x_1, \ldots, x_n)\) is a form in \(C_{n,d} \setminus \Sigma C_{n,d}\), then

\[
p(x_1, \ldots, x_{n+1}) = p(x_1, \ldots, x_n) + x_{n+1}^d
\]

belongs to \(C_{n+1,d} \setminus \Sigma C_{n+1,d}\). Convexity of \(\tilde{p}\) is obvious since it is a sum of convex functions. The fact that \(\tilde{p}\) is not sos-convex can also easily be seen from the block diagonal structure of the Hessian of \(\tilde{p}\): if the Hessian of \(\tilde{p}\) were to factor, it would imply that the Hessian of \(p\) should also factor. The argument for going from \(C_{n,d} \setminus \Sigma C_{n,d}\) to \(C_{n+1,d} \setminus \Sigma C_{n+1,d}\) is identical.

Unfortunately, an argument for increasing the degree of convex but not sos-convex forms seems to be significantly more difficult to obtain. In fact, we have been unable to come up with a natural operation that would produce a form in \(C_{n,d} \setminus C_{n,d+2}\) from a form in \(C_{n,d} \setminus \Sigma C_{n,d}\). We will instead take a different route: we are going to present a general procedure for going from a form in \(P_{n,d} \setminus \Sigma_{n,d}\) to a form in \(C_{n,d+2} \setminus \Sigma C_{n,d+2}\). This will serve our purpose of constructing convex but not sos-convex forms in higher degrees and is perhaps also of independent interest in itself. For instance, it can be used to construct convex but not sos-convex forms that inherit structural properties (e.g., symmetry) of the known examples of psd but not sos forms. The procedure is constructive modulo the value of two positive constants (\(\gamma\) and \(\alpha\) below) whose existence will be shown nonconstructively.\(^9\)

Although the proof of the general case is no different, we present this construction for the case \(n = 3\). The reason is that it suffices for us to construct forms in \(C_{3,d} \setminus \Sigma C_{3,d}\) for \(d\) even and \(\geq 8\). These forms together with the two forms in \(C_{3,6} \setminus \Sigma C_{3,6}\) and \(C_{4,4} \setminus \Sigma C_{4,4}\) presented in (5.1) and (5.5) and with the simple procedure for increasing the number of variables cover all the values of \(n\) and \(d\) for which convex but not sos-convex forms exist.

For the remainder of this section, let \(x := (x_1, x_2, x_3)^T\) and \(y := (y_1, y_2, y_3)^T\).

**Theorem 5.10.** Let \(m := m(x)\) be a ternary form of degree \(d\) (with \(d\) necessarily even and \(\geq 6\)) satisfying the following three requirements:

- R1. \(m\) is positive definite.
- R2. \(m\) is not an sum of squares.
- R3. The Hessian \(H_m\) of \(m\) is positive definite at the point \((1, 0, 0)^T\).

Let \(g := g(x_2, x_3)\) be any bivariate form of degree \(d + 2\) whose Hessian is positive definite.

Then, there exists a constant \(\gamma > 0\) such that the form \(f\) of degree \(d + 2\) given by

\[
f(x) = \int_0^{x_1} \int_0^s m(t, x_2, x_3) dt ds + \gamma g(x_2, x_3)
\]

is convex but not sos-convex.

The form \(f\) in (5.8) is just a specific polynomial that when differentiated twice with respect to \(x_1\) gives \(m\). The reason for this construction will become clear once

---

\(^8\)The choice of multipliers in (5.3) and (5.7) is motivated by a result of Reznick in [39].

\(^9\)The procedure can be thought of as a generalization of the approach in our earlier work in [5].
we present the proof of this theorem. Before we do that, let us comment on how one can get examples of forms \( m \) and \( g \) that satisfy the requirements of the theorem. The choice of \( g \) is in fact very easy. We can, e.g., take

\[
g(x_2, x_3) = (x_2^2 + x_3^2)^{d+2},
\]

which has a positive definite Hessian. As for the choice of \( m \), essentially any psd but not sos ternary form can be turned into a form that satisfies requirements R1, R2, and R3. Indeed if the Hessian of such a form is positive definite at just one point, then that point can be taken to \((1, 0, 0)^T\) by a change of coordinates without changing the properties of being psd and not sos. If the form is not positive definite, then it can made so by adding a small enough multiple of a positive definite form to it. For concreteness, we construct in the next lemma a family of forms that together with the above theorem will give us convex but not sos-convex ternary forms of any degree \( \geq 8 \).

**Lemma 5.11.** For any even degree \( d \geq 6 \), there exists a constant \( \alpha > 0 \) such that the form

\[
(5.9) \quad m(x) = x_1^{d-6}(x_1^2x_2^4 + x_1^4x_2^2 - 3x_1^2x_2^2x_3^2 + x_3^6) + \alpha(x_1^2 + x_2^2 + x_3^2) \frac{d}{2}
\]

satisfies requirements R1, R2, and R3 of Theorem 5.10.

**Proof.** The form

\[
x_1^2x_2^4 + x_1^4x_2^2 - 3x_1^2x_2^2x_3^2 + x_3^6
\]

is the familiar Motzkin form in (2.1) that is psd but not sos [29]. For any even degree \( d \geq 6 \), the form

\[
x_1^{d-6}(x_1^2x_2^4 + x_1^4x_2^2 - 3x_1^2x_2^2x_3^2 + x_3^6)
\]

is a form of degree \( d \) that is clearly still psd and less obviously still not sos; see [40]. This together with the fact that \( \Sigma_{n,d} \) is a closed cone implies existence of a small positive value of \( \alpha \) for which the form \( m \) in (5.9) is positive definite but not an sum of squares, hence satisfying requirements R1 and R2.

Our next claim is that for any positive value of \( \alpha \), the Hessian \( H_m \) of the form \( m \) in (5.9) satisfies

\[
(5.10) \quad H_m(1, 0, 0) = \begin{bmatrix} c_1 & 0 & 0 \\ 0 & c_2 & 0 \\ 0 & 0 & c_3 \end{bmatrix}
\]

for some positive constants \( c_1, c_2, c_3 \), therefore also passing requirement R3. To see the above equality, first note that since \( m \) is a form of degree \( d \), its Hessian \( H_m \) will have entries that are forms of degree \( d - 2 \). Therefore, the only monomials that can survive in this Hessian after setting \( x_2 \) and \( x_3 \) to zero are multiples of \( x_1^{d-2} \). It is easy to see that an \( x_1^{d-2} \) monomial in an off-diagonal entry of \( H_m \) would lead to a monomial in \( m \) that is not even. On the other hand, the form \( m \) in (5.9) only has even monomials. This explains why the off-diagonal entries of the right-hand side of (5.10) are zero. Finally, we note that for any positive value of \( \alpha \), the form \( m \) in (5.9) includes positive multiples of \( x_1^d, x_1^{d-2}x_2^2 \), and \( x_1^{d-2}x_2^2 \), which lead to positive multiples of \( x_1^{d-2} \) on the diagonal of \( H_m \). Hence, \( c_1, c_2, \) and \( c_3 \) are positive.

Next, we state two lemmas that will be employed in the proof of Theorem 5.10.
Lemma 5.12. Let $m$ be a trivariate form satisfying requirements R1 and R3 of Theorem 5.10. Let $H_{\hat{m}}$ denote the Hessian of the form $\int_0^{x_1} \int_0^{x_2} m(t, x_2, x_3)dt ds$. Then, there exists a positive constant $\delta$ such that
\[
y^T H_{\hat{m}}(x)y > 0\]
on the set
\[(5.11) \quad S := \{(x, y) \mid ||x|| = 1, ||y|| = 1, \ (x_2^2 + x_3^2 < \delta \text{ or } y_2^2 + y_3^2 < \delta)\}.
\]

Proof. We observe that when $y_2^2 + y_3^2 = 0$, we have
\[
y^T H_{\hat{m}}(x)y = y_3^2 m(x),
\]
which by requirement R1 is positive when $||x|| = ||y|| = 1$. By continuity of the form $y^T H_{\hat{m}}(x)y$, we conclude that there exists a small positive constant $\delta_y$ such that $y^T H_{\hat{m}}(x)y > 0$ on the set
\[
S_y := \{(x, y) \mid ||x|| = 1, ||y|| = 1, \ y_2^2 + y_3^2 < \delta_y\}.
\]
Next, we leave it to the reader to check that
\[
H_{\hat{m}}(1, 0, 0) = \frac{1}{d(d-1)} H_m(1, 0, 0).
\]
Therefore, when $x_2^2 + x_3^2 = 0$, requirement R3 implies that $y^T H_{\hat{m}}(x)y$ is positive when $||x|| = ||y|| = 1$. Appealing to continuity again, we conclude that there exists a small positive constant $\delta_x$ such that $y^T H_{\hat{m}}(x)y > 0$ on the set
\[
S_x := \{(x, y) \mid ||x|| = 1, ||y|| = 1, \ x_2^2 + x_3^2 < \delta_x\}.
\]
If we now take $\delta = \min\{\delta_y, \delta_x\}$, the lemma is established.

The last lemma that we need has already been proved in our earlier work in [5].

Lemma 5.13 (see [5]). All principal minors of an sos-matrix are sos polynomials.\textsuperscript{10}

We are now ready to prove Theorem 5.10.

Proof of Theorem 5.10. We first prove that the form $f$ in (5.8) is not sos-convex. By Lemma 5.13, if $f$ was sos-convex, then all diagonal elements of its Hessian would have to be sos polynomials. On the other hand, we have from (5.8) that
\[
\frac{\partial f(x)}{\partial x_1 \partial x_1} = m(x),
\]
which by requirement R2 is not sos. Therefore $f$ is not sos-convex.

It remains to show that there exists a positive value of $\gamma$ for which $f$ becomes convex. Let us denote the Hessians of $f$, $\int_0^{x_1} \int_0^{x_2} m(t, x_2, x_3)dt ds$, and $g$ by $H_f$, $H_{\hat{m}}$, and $H_g$, respectively. So, we have
\[
H_f(x) = H_{\hat{m}}(x) + \gamma H_g(x_2, x_3).
\]
\textsuperscript{10}As a side note, we remark that the converse of Lemma 5.13 is not true even for polynomial matrices that are valid Hessians. For example, all seven principal minors of the $3 \times 3$ Hessian of the form $f$ in (5.1) are sos polynomials, even though this Hessian is not an sos-matrix.
(Here, $H_g$ is a $3 \times 3$ matrix whose first row and column are zeros.) Convexity of
$f$ is of course equivalent to nonnegativity of the form $y^T H_f(x)y$. Since this form
is bihomogeneous in $x$ and $y$, it is nonnegative if and only if $y^T H_f(x)y \geq 0$ on the
bisphere
\[ \mathcal{B} := \{(x, y) \mid \|x\| = 1, \|y\| = 1\}. \]
Let us decompose the bisphere as
\[ \mathcal{B} = \mathcal{S} \cup \bar{\mathcal{S}}, \]
where $\mathcal{S}$ is defined in (5.11) and
\[ \bar{\mathcal{S}} := \{(x, y) \mid \|x\| = 1, \|y\| = 1, x_2^2 + x_3^2 \geq \delta, y_2^2 + y_3^2 \geq \delta\}. \]
Lemma 5.12 together with positive definiteness of $H_g$ imply that $y^T H_f(x)y$ is positive
on $\mathcal{S}$. As for the set $\bar{\mathcal{S}}$, let
\[ \beta_1 = \min_{x, y, \in \mathcal{S}} y^T H_{\tilde{m}}(x)y \]
and
\[ \beta_2 = \min_{x, y, \in \bar{\mathcal{S}}} y^T H_g(x_2, x_3)y. \]
By the assumption of positive definiteness of $H_g$, we have $\beta_2 > 0$. If we now let
\[ \gamma > \frac{|\beta_1|}{\beta_2}, \]
then
\[ \min_{x, y, \in \bar{\mathcal{S}}} y^T H_f(x)y > \beta_1 + \frac{|\beta_1|}{\beta_2} \beta_2 \geq 0. \]
Hence $y^T H_f(x)y$ is nonnegative (in fact positive) everywhere on $\mathcal{B}$ and the proof is
completed.

Finally, we provide an argument for existence of bivariate polynomials of degree
8, 10, 12, . . . that are convex but not sos-convex.

**Corollary 5.14.** Consider the form $f$ in (5.8) constructed as described in
Theorem 5.10. Let
\[ \tilde{f}(x_1, x_2) = f(x_1, x_2, 1). \]
Then, $\tilde{f}$ is convex but not sos-convex.

**Proof.** The polynomial $\tilde{f}$ is convex because it is the restriction of a convex
function. It is not difficult to see that
\[ \frac{\partial \tilde{f}(x_1, x_2)}{\partial x_1 \partial x_1} = m(x_1, x_2, 1), \]
which is not sos. Therefore from Lemma 5.13 $\tilde{f}$ is not sos-convex.

Corollary 5.14 together with the two polynomials in $\tilde{C}_{2, \delta} \setminus \Sigma C_{2, \delta}$ and $\tilde{C}_{3, \delta} \setminus \Sigma C_{3, \delta}$
presented in (5.2) and (5.6) and with the simple procedure for increasing the number
of variables described at the beginning of subsection 5.2.2 covers all the values of $n$
and $d$ for which convex but not sos-convex polynomials exist.
6. Concluding remarks and an open problem. To conclude our paper, we would like to point out some similarities between nonnegativity and convexity that deserve attention: (i) both nonnegativity and convexity are properties that hold only for even degree polynomials; (ii) for quadratic forms, nonnegativity is in fact equivalent to convexity; (iii) both notions are NP-hard to check exactly for degree 4 and larger; and, most strikingly, (iv) nonnegativity is equivalent to sum of squares exactly in dimensions and degrees where convexity is equivalent to sos-convexity. It is unclear to us whether there can be a deeper and more unifying reason explaining these observations, in particular the last one, which was the main result of this paper.

Another intriguing question is to investigate whether one can give a direct argument proving the fact that \( \Sigma C_{n,d} = \tilde{C}_{n,d} \) if and only if \( \Sigma C_{n+1,d} = C_{n+1,d} \). This would eliminate the need for studying polynomials and forms separately and in particular would provide a short proof of the result \( \Sigma_{3,4} = C_{3,4} \) given in [1].

Finally, an open problem related to this work is to find an explicit example of a convex form that is not an sum of squares. Blekherman [8] has shown via volume arguments that for degree \( d \geq 4 \) and asymptotically for large \( n \) such forms must exist, although no examples are known. In particular, it would be interesting to determine the smallest value of \( n \) for which such a form exists. We know from Lemma 3.2 that a convex form that is not sos must necessarily be not sos-convex. Although our several constructions of convex but not sos-convex polynomials pass this necessary condition, the polynomials themselves are all sos. The question is particularly interesting from an optimization viewpoint because it implies that the well-known sum of squares relaxation for minimizing polynomials [46], [32] is not always exact even for the easy case of minimizing convex polynomials.

Appendix A. Certificates complementing the proof of Theorem 5.8. Let \( x := (x_1, x_2, x_2)^T \), \( y := (y_1, y_2, y_3)^T \), \( \tilde{x} := (x_1, x_2)^T \), \( \tilde{y} := (y_1, y_2)^T \), and let \( f, \tilde{f}, H_f \), and \( H_{\tilde{f}} \) be as in the proof of Theorem 5.8. This appendix proves that the form \( (x_1^2 + x_2^2) \cdot y^T H_f(x)y \) in (5.3) is sos and that the polynomial \( \tilde{y}^T H_{\tilde{f}}(\tilde{x})\tilde{y} \) in (5.4) is not sos, hence proving respectively that \( f \) is convex and \( \tilde{f} \) is not sos-convex.

A rational sos decomposition of \( (x_1^2 + x_2^2) \cdot y^T H_f(x)y \), which is a form in six variables of degree 8, is as follows:

\[
(x_1^2 + x_2^2) \cdot y^T H_f(x)y = \frac{1}{84} z^T Q z,
\]

where \( z \) is the vector of monomials

\[
z = [x_2 x_3^2 y_3, x_2 x_3^2 y_2, x_2 x_3^2 y_1, x_2^2 x_3 y_3, x_2^2 x_3 y_2, x_2^2 x_3 y_1, x_2^3 y_3, x_2^3 y_2, x_2^3 y_1, x_1 x_3^2 y_3, x_1 x_3^2 y_2, x_1 x_3^2 y_1, x_1 x_2 x_3 y_3, x_1 x_2 x_3 y_2, x_1 x_2 x_3 y_1, x_1 x_2^2 y_3, x_1 x_2^2 y_2, x_1 x_2^2 y_1, x_1 x_3^2 y_3, x_1 x_3^2 y_2, x_1 x_3^2 y_1, x_1 x_2 x_3 y_3, x_1 x_2 x_3 y_2, x_1 x_2 x_3 y_1, x_1 x_2^2 y_3, x_1 x_2^2 y_2, x_1 x_2^2 y_1, x_1 x_3 y_3, x_1 x_3 y_2, x_1 x_3 y_1, x_1^2 x_2 y_3, x_1^2 x_2 y_2, x_1^2 x_2 y_1, x_1^2 y_3, x_1^2 y_2, x_1^2 y_1, x_1^3 y_3, x_1^3 y_2, x_1^3 y_1]^T
\]

and \( Q \) is the \( 27 \times 27 \) positive definite matrix\(^{\text{11}}\) presented on the next page

\[
Q = \begin{bmatrix}
Q_1 & Q_2
\end{bmatrix},
\]

\(^{\text{11}}\)Whenever we state a matrix is positive definite, this claim is backed up by a rational \( LDL^T \) factorization of the matrix that the reader can find online at http://aaa.lids.mit.edu/software or at http://arxiv.org/abs/1111.4587.
Next, we prove that the polynomial $\tilde{y}^T H_f(\tilde{x}) \tilde{y}$ in (5.4) is not sos. Let us first present this polynomial and give it a name:

$$
t(\tilde{x}, \tilde{y}) := \tilde{y}^T H_f(\tilde{x}) \tilde{y} = 294x_1x_2y_2^2 - 6995x_2^2y_1y_2 - 10200x_1y_1y_2 - 4356x_1^2x_2y_1^2 - 2904x_1^3y_1y_2
- 11475x_1^2y_2^2 + 13680x_1^2y_1y_2 + 4764x_1x_2y_1^2 + 4764x_1^2y_1y_2 + 6429x_1x_2y_2^2
+ 294x_2^2y_1y_2 - 13990x_1x_2y_2^2 - 12123x_1^2x_2y_2^2 - 3872x_2y_1y_2 + \frac{2143}{2}x_1^4y_2^2
+ 20520x_1^2y_2^2 + 29076x_1x_2y_1y_2 - 24246x_1^2x_2y_1y_2 + 14901x_1^3y_1y_2
+ 15039x_1^2y_1y_2 + 8572x_2y_1y_2 + \frac{44703}{4}x_1^2x_2y_2^2 + 5013x_1^3x_2y_2^2
+ 362y_1y_2 - 12360x_2y_2^2 - 5100x_2y_2^2 + \frac{147511}{4}x_1^2y_2^2 + 7269x_2y_1y_2 - 45025x_2^2y_2^2
+ \frac{772965}{32}x_2y_2^2 + \frac{14901}{8}x_1^2y_2^2 - 1936x_1y_2^2 - 84x_1y_2^2 + \frac{3817}{4}y_2^2 + 1442y_2^2
+ 7269x_1^2y_2^2 + 4356x_1y_2^2 - 3825x_1y_2^2 - 180x_1y_2^2 + 2310x_1^2y_2^2
+ 5013x_1^2y_1y_2 - 22950x_1^2x_2y_2 - 1505x_1^3y_1y_2 - 4041x_2^2y_2^2 - 3010x_2^3y_2^2.
$$

Note that $t$ is a polynomial in four variables of degree 6 that is quadratic in $\tilde{y}$. Let us denote the cone of sos polynomials in four variables $(\tilde{x}, \tilde{y})$ that have degree 6 and are quadratic in $\tilde{y}$ by $\Sigma_{4,6}$ and its dual cone by $\tilde{\Sigma}_{4,6}$. Our proof will simply proceed by presenting a dual functional $\xi \in \tilde{\Sigma}_{4,6}^*$ that takes a negative value on the polynomial $t$. We fix the following ordering of monomials in what follows:

\begin{align}
\langle v, x \rangle &= [y_2^2, y_1y_2, y_1^2, x_2y_2, x_2y_1y_2, x_2y_1^2, x_2^2y_2, x_2y_1y_2, x_2y_1^2, x_2^2y_1, x_1^3y_1, x_1^2y_1, x_1y_2, x_1y_1y_2, x_1^2y_2, x_1y_1y_2, x_1y_2, x_1^2y_2, x_1^3y_2, x_1^2y_1y_2, x_1^2y_2, x_1y_2, x_1^2y_2, x_1y_1y_2, x_1y_2, x_1^2y_2, x_1y_1, x_1y_2, x_1^2y_2, x_1^2y_2, x_1^3y_2, x_1^2y_1y_2, x_1^2y_2, x_1y_2, x_1^2y_2, x_1y_1y_2, x_1^2y_2, x_1^2y_2, x_1^3y_2]
\end{align}

Let $\tilde{t}$ represent the vector of coefficients of $t$ ordered according to the list of monomials above, i.e., $t = \tilde{t}^T v$. Using the same ordering, we can represent our dual functional $\xi$ with the vector

\begin{align}
\end{align}

We have

$$
\langle \xi, t \rangle = c^T \tilde{t} = -\frac{36457}{16} < 0.
$$

On the other hand, we claim that $\xi \in \tilde{\Sigma}_{4,6}^*$; i.e., for any form $w \in \tilde{\Sigma}_{4,6}$, we should have

\begin{align}
\langle \xi, w \rangle = c^T \tilde{w} \geq 0,
\end{align}

where $\tilde{w}$ here denotes the coefficients of $w$ listed according to the ordering in (A.1). Indeed, if $w$ is sos, then it can be written in the form

$$
w(x) = \tilde{z}^T \tilde{Q} \tilde{z} = \text{Tr } \tilde{Q} \cdot \tilde{z} \tilde{z}^T
$$
for some symmetric positive semidefinite matrix \( \tilde{Q} \) and a vector of monomials

\[
\tilde{z} = [y_2, y_1, x_2 y_2, x_2 y_1, x_1 y_2, x_1 y_1, x_2^2 y_2, x_2^2 y_1, x_1 x_2 y_2, x_1 x_2 y_1, x_1^2 y_2, x_1^2 y_1]^T.
\]

It is not difficult to see that

\[
\begin{align*}
\tilde{z}^T \tilde{w} &= \text{Tr} \tilde{Q} \cdot (\tilde{z} \tilde{z}^T)|_c,
\end{align*}
\]

where by \((\tilde{z} \tilde{z}^T)|_c\) we mean a matrix where each monomial in \(\tilde{z} \tilde{z}^T\) is replaced with the corresponding element of the vector \(c\). This yields the matrix

\[
(\tilde{z} \tilde{z}^T)|_c =
\begin{bmatrix}
19338 & -2485 & 6219 & -4461 & 2060 & 3506 & 4290 & -5745 & 366 & -2698 & 6122 & 659 \\
-2485 & 17155 & -4461 & 11202 & 3506 & 5116 & -5745 & 13748 & -2698 & 6231 & 659 & 7057 \\
-4461 & 11202 & -5745 & 13748 & -2698 & 6231 & -5404 & 13227 & -2324 & 4607 & 1238 & 1752 \\
6122 & 659 & 1646 & 1238 & -200 & 1577 & 2797 & -940 & -513 & -3747 & 15261 & 220 \\
\end{bmatrix},
\]

which is positive definite. Therefore, (A.3) along with the fact that \(\tilde{Q}\) is positive semidefinite implies that (A.2) holds. This completes the proof.
