Amplitude analysis and branching fraction measurement of $B^{0} \rightarrow J/K^{+}K^{-}$
Amplitude analysis and branching fraction measurement of $\bar{B}_s^0 \to J/\psi K^+ K^-$

R. Aaij et al.*
(LHCb Collaboration)

(Received 5 February 2013; published 8 April 2013)

An amplitude analysis of the final state structure in the $\bar{B}_s^0 \to J/\psi K^+ K^-$ decay mode is performed using 1.0 fb$^{-1}$ of data collected by the LHCb experiment in 7 TeV center-of-mass energy $pp$ collisions produced by the LHC. A modified Dalitz plot analysis of the final state is performed using both the invariant mass spectra and the decay angular distributions. Resonant structures are observed in the $K^+ K^-$ mass spectrum as well as a significant nonresonant $S$-wave contribution over the entire $K^+ K^-$ mass range. The largest resonant component is the $\phi(1020)$, accompanied by $f_0(980), f'_0(1525)$, and four additional resonances. The overall branching fraction is measured to be $\mathcal{B}(\bar{B}_s^0 \to J/\psi K^+ K^-) = (7.70 \pm 0.08 \pm 0.39 \pm 0.60) \times 10^{-4}$, where the first uncertainty is statistical, the second systematic, and the third due to the ratio of the number of $\bar{B}_s^0$ to $B^-$ mesons produced. The mass and width of the $f'_0(1525)$ are measured to be $1522.2 \pm 2.8^{+3.3}_{-2.3}$ MeV and $84 \pm 6^{+10}_{-5}$ MeV, respectively. The final state fractions of the other resonant states are also reported.

I. INTRODUCTION

The study of $\bar{B}_s^0$ decays to $J/\psi h^+ h^-$, where $h$ is either a pion or kaon, has been used to measure mixing-induced CP violation in $\bar{B}_s^0$ decays [1–7]. In order to best exploit these decays, a better understanding of the final state composition is necessary. This study has been reported for the $\bar{B}_s^0 \to J/\psi \pi^+ \pi^-$ channel [8]. Here we perform a similar analysis for $\bar{B}_s^0 \to J/\psi K^+ K^-$. While a large $\phi(1020)$ contribution is well-known [9] and the $f'_0(1525)$ component has been recently observed [10] and confirmed [11], other components have not heretofore been identified including the sources of $S$-wave contributions [12]. The tree-level Feynman diagram for the process is shown in Fig. 1.

In this paper the $J/\psi K^+$ and $K^+ K^-$ mass spectra and decay angular distributions are used to study resonant and nonresonant structures. This differs from a classical “Dalitz plot” analysis [13] since the $J/\psi$ meson has spin-1, and its three helicity amplitudes must be considered.

II. DATA SAMPLE AND DETECTOR

The event sample is obtained using 1.0 fb$^{-1}$ of integrated luminosity collected with the LHCb detector [14] using $pp$ collisions at a center-of-mass energy of 7 TeV. The detector is a single-arm forward spectrometer covering the pseudorapidity range $2 < \eta < 5$, designed for the study of particles containing $b$ or $c$ quarks. Components include a high-precision tracking system consisting of a silicon-strip vertex detector surrounding the $pp$ interaction region, a large-area silicon strip detector located upstream of a dipole magnet with a bending power of about 4 Tm, and three stations of silicon strip detectors and straw drift tubes placed downstream. The combined tracking system has momentum$^2$ resolution $\Delta p/p$ that varies from 0.4% at 5 GeV to 0.6% at 100 GeV. The impact parameter (IP) is defined as the minimum distance of approach of the track with respect to the primary vertex. For tracks with large transverse momentum with respect to the proton beam direction, the IP resolution is approximately 20 µm. Charged hadrons are identified using two ring-imaging Cherenkov detectors. Photon, electron, and hadron candidates are identified by a calorimeter system consisting of scintillating-pad and preshower detectors, an electromagnetic calorimeter, and a hadronic calorimeter. Muons are identified by a system composed of alternating layers of iron and multiwire proportional chambers.

The trigger [15] consists of a hardware stage, based on information from the calorimeter and muon systems, followed by a software stage that applies a full event reconstruction. Events selected for this analysis are triggered by a $J/\psi \to \mu^+ \mu^-$ decay, where the $J/\psi$ is required at the software level to be consistent with coming from the decay of a $\bar{B}_s^0$ meson by use either of IP requirements or detachment of the $J/\psi$ from the primary vertex. Monte Carlo simulations are performed using PYTHIA [16] with the specific tuning given in Ref. [17], and the LHCb detector description based on GEANT4 [18] described in Ref. [19]. Decays of $B$ mesons are based on EVTGEN [20].

III. SIGNAL SELECTION AND BACKGROUNDS

We select $\bar{B}_s^0 \to J/\psi K^+ K^-$ candidates trying to simultaneously maximize the signal yield and reduce the

background. Candidate $J/\psi \rightarrow \mu^+\mu^-$ decays are combined with a pair of kaon candidates of opposite charge and then required that all four tracks are consistent with coming from a common decay point. To be considered a $J/\psi \rightarrow \mu^+\mu^-$ candidate, particles identified as muons of opposite charge are required to have transverse momentum, $p_T$, greater than 500 MeV and form a vertex with fit $\chi^2$ per number of degrees of freedom (ndf) less than 11. These requirements give rise to a large $J/\psi$ signal over a small background [21]. Only candidates with a dimuon invariant mass between $-48$ MeV to $+43$ MeV relative to the observed $J/\psi$ mass peak are selected. The asymmetric requirement is due to final-state electromagnetic radiation. The twmuons are subsequently kinematically constrained to the known $J/\psi$ mass [9].

Our ring-imaging Cherenkov system allows for the possibility of positively identifying kaon candidates. Charged tracks produce Cherenkov photons whose emission angles are compared with those expected for electrons, pions, kaons, or protons and a likelihood for each species is then computed. To identify a particular species, the difference of the logarithm of the likelihoods for two particle hypotheses (DLL) is computed. There are two criteria used: loose corresponds to DLL $(K-\pi) > 0$, while tight has DLL $(K-\pi) > 10$ and DLL $(K-p) > -3$. Unless stated otherwise, we require the tight criterion for kaon selection.

We select candidate $K^+K^-$ combinations if each particle is inconsistent with having been produced at the primary vertex. For this test we require that the $\chi^2$ formed by using the hypothesis that the IP is zero be greater than 9 for each track. Furthermore, each kaon must have $p_T > 250$ MeV and the scalar sum of the $p_T$ of the kaon candidates must be greater than 900 MeV. To select $B_s^0$ candidates, we further require that the two kaon candidates form a vertex with $\chi^2 < 10$, and that they form a candidate $B_s^0$ vertex with the $J/\psi$ where the vertex fit $\chi^2$/ndf < 5. We require that this $B_s^0$ vertex be more than 1.5 mm from the primary vertex, and the angle between the $B_s^0$ momentum vector and the vector from the primary vertex to the $B_s^0$ vertex must be less than 11.8 mrad.

The $B_s^0$ candidate invariant mass distribution is shown in Fig. 2. The vertical lines indicate the signal and sideband regions, where the signal region extends to $\pm 20$ MeV around the nominal $B_s^0$ mass [9] and the sidebands extend from 35 MeV to 60 MeV on either side of the peak. The small peak near 5280 MeV results from $B_s^0$ decays and will be subject to future investigation.

The background consists of combinations of tracks, which have a smooth mass shape through the $J/\psi K^+K^-$ region and peaking contributions caused by the reflection of specific decay modes where a pion is misidentified as a kaon. The reflection background that arises from the decay $B_s^0 \rightarrow J/\psi K^+\pi^+$, where the $\pi^+$ is misidentified as a $K^+$, is determined from the number of $B_s^0$ candidates in the control region $25–200$ MeV above the $B_s^0$ mass peak.

For each of the candidates in the $J/\psi K^+K^-$ control region, we reassign each of the two kaons in turn to the pion mass hypothesis. The resulting $J/\psi K^+K^-$ invariant mass distribution is shown in Fig. 3. The peak at the $B_s^0$ mass has $906 \pm 51$ candidates, determined by fitting the data to a Gaussian function for the signal, and a polynomial function for the background. From these events we estimate the number in the $B_s^0$ signal region, based on a simulation of the shape of the reflected distribution as a...
function of $J/\psi K^- K^+$ mass. Using simulated $B^0 \rightarrow J/\psi K^{*0}(892)$ and $B^0 \rightarrow J/\psi K^*_2(1430)$ samples, we calculate $309 \pm 17$ reflection candidates within $\pm 20$ MeV of the $B^0_T$ peak. This number is used as a constraint in the mass fit described below.

To determine the number of $B^0_T$ signal candidates we perform a fit to the candidate $J/\psi K^+ K^-$ invariant mass spectrum shown in Fig. 4. The fit function is the sum of the $B^0_T$ signal component, combinatorial background, and the contribution from the $B^0 \rightarrow J/\psi K^- \pi^+$ reflections. The signal is modeled by a double-Gaussian function with a common mean. The combinatorial background is described by a linear function. The reflection background is constrained as described above. The mass fits give 19, 195 $\pm$ 10 signal together with $894 \pm 24$ combinatorial background candidates within $\pm 20$ MeV of the $B^0_T$ mass peak.

We use the decay $B^- \rightarrow J/\psi K^-$ as the normalization channel for branching fraction determinations. The selection criteria are similar to those used for $J/\psi K^+ K^-$, except for particle identification as here a loose kaon identification criterion is used. Figure 5 shows the $J/\psi K^-$ mass distribution. The signal is fit with a double-Gaussian function and a linear function is used to fit the combinatorial background. There are 342, 786 $\pm 661$ signal and 10, 195 $\pm 134$ background candidates within $\pm 20$ MeV of the $B^-$ peak.

IV. ANALYSIS FORMALISM

One of the goals of this analysis is to determine the intermediate states in $B^0_S \rightarrow J/\psi K^+ K^-$ decay within the context of an isobar model [22,23], where we sum the resonant and nonresonant components testing if they explain the invariant mass squared and angular distributions. We also determine the absolute branching fractions of $B^0_S \rightarrow J/\psi \phi(1020)$ and $B^0_S \rightarrow J/\psi f_2^+(1525)$ final states and the mass and width of the $f_2^+(1525)$ resonance. Another important goal is to understand the S-wave content in the $\phi(1020)$ mass region.

Four variables completely describe the decay of $B^0_S \rightarrow J/\psi K^+ K^-$ with $J/\psi \rightarrow \mu^+ \mu^-$. Two are the invariant mass squared of $J/\psi K^+$, $s_{12} = m^2(J/\psi K^+)$, and the invariant mass squared of $K^+ K^-$, $s_{23} = m^2(K^+ K^-)$. The other two are the $J/\psi$ helicity angle, $\theta_{J/\psi}$, which is the angle of the $\mu^+$ in the $J/\psi$ rest frame with respect to the $J/\psi$ direction in the $B^0_S$ rest frame, and the angle between the $J/\psi$ and $K^+ K^-$ decay planes, $\chi$, in the $B^0_S$ rest frame. To simplify the probability density function (PDF), we analyze the decay process after integrating over the angular variable $\chi$, which eliminates several interference terms.

A. The model for $B^0_S \rightarrow J/\psi K^+ K^-$

In order to perform an amplitude analysis a PDF must be constructed that models correctly the dynamical and kinematic properties of the decay. The PDF is separated into two components, one describing signal, $S$, and the other background, $B$. The overall PDF given by the sum is

$$F(s_{12}, s_{23}, \theta_{J/\psi}) = 1 - \frac{f_{\text{com}} - f_{\text{refl}}}{N_{\text{sig}}} e(s_{12}, s_{23}, \theta_{J/\psi})$$

$$\times S(s_{12}, s_{23}, \theta_{J/\psi}) + B(s_{12}, s_{23}, \theta_{J/\psi}),$$

(1)

where $e$ is the detection efficiency. The background is described by the sum of combinatorial background, $C$, and reflection, $R$, functions

$$B(s_{12}, s_{23}, \theta_{J/\psi}) = \frac{f_{\text{com}}}{N_{\text{com}}} C(s_{12}, s_{23}, \theta_{J/\psi})$$

$$+ \frac{f_{\text{refl}}}{N_{\text{refl}}} R(s_{12}, s_{23}, \theta_{J/\psi}),$$

(2)
where $f_{\text{com}}$ and $f_{\text{refl}}$ are the fractions of the combinatorial background and reflection, respectively, in the fitted region. The fractions $f_{\text{com}}$ and $f_{\text{refl}}$ obtained from the mass fit are fixed for the subsequent analysis.

The normalization factors are given by

$$
\mathcal{N}_{\text{sig}} = \int e(s_{12}, s_{32}, \theta_{J/\psi}) S(s_{12}, s_{32}, \theta_{J/\psi})
\times ds_{12} ds_{32} ds_{23} d \cos \theta_{J/\psi},
$$

$$
\mathcal{N}_{\text{com}} = \int C(s_{12}, s_{32}, \theta_{J/\psi}) ds_{12} ds_{32} ds_{23} d \cos \theta_{J/\psi},
$$

$$
\mathcal{N}_{\text{refl}} = \int R(s_{12}, s_{32}, \theta_{J/\psi}) ds_{12} ds_{32} ds_{23} d \cos \theta_{J/\psi}.
$$

This formalism is similar to that used by Belle in their analysis of $B^0 \to K^- \pi^+ \chi_{c1}$ [24], and later used by LHCb for the analysis of $B^0 \to J/\psi \pi^+ \pi^-$ [8].

The invariant mass squared of $J/\psi K^+$ versus $K^+ K^-$ is shown in Fig. 6 for $B^0 \to J/\psi K^+ K^-$ candidates. No structure is seen in $m^2(J/\psi K^+)$, beyond the decay of $B^0$ mesons. There are however a few horizontal bands in the $K^+ K^-$ mass squared spectrum, the most prominent of which correspond to the $\phi(1020)$ and $J/\psi(1525)$ resonances. These and other structures in $m^2(K^+ K^-)$ are now examined.

The signal function is given by the coherent sum over resonant states that decay into $K^+ K^-$, plus a possible nonresonant S-wave contribution

$$
S(s_{12}, s_{32}, \theta_{J/\psi}) = \sum_{\lambda = 0, \pm 1} \left| \sum_i a^R_{\lambda} e^{i\phi^R_{\lambda}} \mathcal{A}^R_{\lambda}(s_{12}, s_{32}, \theta_{J/\psi}) \right|^2,
$$

where $\mathcal{A}^R_{\lambda}(s_{12}, s_{32}, \theta_{J/\psi})$ describes the decay amplitude via an intermediate resonance state $R$, with helicity $\lambda$. Note that the $J/\psi$ has the same helicity as the intermediate $K^+ K^-$ resonance. Each $R_\lambda$ has an associated amplitude strength $a^R_{\lambda}$ and a phase $\phi^R_{\lambda}$ for each helicity state $\lambda$. The amplitude for resonance $R$, for each $i$, is given by

$$
\mathcal{A}^R_{\lambda}(s_{12}, s_{32}, \theta_{J/\psi}) = F^{(L_0)}_{R} A_R(s_{32}) F^{(L_0)}_{R} T_\lambda(\theta_{KK}) \left( \frac{P_R}{m_R} \right)^{L_0} \Theta_\lambda(\theta_{J/\psi}),
$$

where $P_R$ is the momentum of either of the two kaons in the di-kaon rest frame, $m_R$ is the $B$ mass, $P_B$ is the magnitude of the $J/\psi$ three-momentum in the $B^0$ rest frame, and $F^{(L_0)}_{R}$ and $F^{(L_0)}_{R}$ are the $B^0$ meson and $R$ resonance decay form factors. The orbital angular momenta between the $J/\psi$ and $K^+ K^-$ system is given by $L_B$, and the orbital angular momentum in the $K^+ K^-$ decay is given by $L_R$; the latter

$\frac{1}{2}$ is the angular momentum for resonance $R$, and the other possibilities in the systematic uncertainty.

The Blatt-Weisskopf barrier factors $F^{(L_0)}_{R}$ and $F^{(L_0)}_{R}$ [25] are

$$
F^{(0)} = 1, \quad F^{(1)} = \frac{1 + z_0}{\sqrt{1 + z}},
$$

$$
F^{(2)} = \frac{\sqrt{z_0^2 + 3z_0 + 9}}{\sqrt{z^2 + 3z + 9}}.
$$

For the $B$ meson $z = r^2 P^2_0$, where $r$, the hadron scale, is taken as 5.0 GeV$^{-1}$; for the $R$ resonance $z = r^2 P^2_R$, and $r$ is taken as 1.5 GeV$^{-1}$ [26]. In both cases $z_0 = r^2 P^2_0$ where $P_0$ is the decay daughter momentum at the pole mass; for the $B^0$ decay the $J/\psi$ momentum is used, while for the $R$ resonances the kaon momentum is used.

In the helicity formalism, the angular term, $T_\lambda(\theta_{KK})$ is defined as

$$
T_\lambda(\theta_{KK}) = d_{\lambda}(\theta_{KK}),
$$

where $d$ is the Wigner $d$-function, $J$ is the resonance spin, $\theta_{KK}$ is the helicity angle of the $K^+$ in the $K^+ K^-$ rest frame with respect to the $K^+ K^-$ direction in the $B^0$ rest frame and may be calculated directly from the other variables as

$$
\cos \theta_{KK} = \frac{m^2(J/\psi K^+) - m^2(J/\psi K^-) m(K^+ K^-)}{4P_R F_B m_B}.
$$

The $J/\psi$ helicity dependent term $\Theta_\lambda(\theta_{J/\psi})$ is defined as

FIG. 6. Distribution of $m^2(K^+ K^-)$ versus $m^2(J/\psi K^+)$ for $B^0$ candidate decays within $\pm 20$ MeV of the $B^0$ mass. The horizontal bands result from the $\phi(1020)$ and $f_2^+(1525)$ resonances.
\[ \Theta_\lambda(\theta_{j/\phi}) = \sqrt{\frac{\sin^2 \theta_{j/\phi}}{2}} \quad \text{for } \lambda = 0 \]

\[ = \frac{1 + \cos^2 \theta_{j/\phi}}{2} \quad \text{for } |\lambda| = 1. \]  

(9)

The mass squared shape of each resonance, \( R \) is described by the function \( A_R(s_{23}) \). In most cases this is a Breit-Wigner (BW) amplitude. When a decay channel opens close to the resonant mass, complications arise since the proximity of the second threshold distorts the line shape of the amplitude. The \( f_0(980) \) can decay to either \( \pi\pi \) or \( KK \). While the \( \pi\pi \) channel opens at much lower masses, the \( K^+ K^- \) decay channel opens near the resonant mass. Thus, for the \( f_0(980) \) we use a Flatté model [27] that takes into account these coupled channels.

We describe the BW amplitude for a resonance decaying into two spin-0 particles, labeled as 2 and 3, as

\[ A_R(s_{23}) = \frac{1}{m_R^2 - s_{23} - im_R \Gamma(s_{23})}, \]  

(10)

where \( m_R \) is the resonance mass, \( \Gamma(s_{23}) \) is its energy-dependent width that is parametrized as

\[ \Gamma(s_{23}) = \Gamma_0 \left( \frac{P_R}{P_{R,0}} \right)^{2a+1} \left( \frac{m_R}{s_{23}} \right)^2 F_R. \]  

(11)

Here \( \Gamma_0 \) is the decay width when the invariant mass of the daughter combinations is equal to \( m_R \).

The Flatté mass shape is parametrized as

\[ A_R(s_{23}) = \frac{1}{m_R^2 - s_{23} - im_R (g_{\pi\pi} \rho_{\pi\pi} + g_{KK} \rho_{KK})}, \]  

(12)

where the constants \( g_{\pi\pi} \) and \( g_{KK} \) are the \( f_0(980) \) couplings to \( \pi^+ \pi^- \) and \( K^+ K^- \) final states, respectively. The \( \rho \) factors are given by Lorentz-invariant phase space

\[ \rho_{\pi\pi} = \frac{2}{3} \sqrt{1 - \frac{4m_{\pi}^2}{s_{23}}} + \frac{1}{3} \sqrt{1 - \frac{4m_{\pi}^2}{s_{13}}}, \]  

(13)

\[ \rho_{KK} = \frac{1}{2} \sqrt{1 - \frac{4m_{K}^2}{s_{23}}} + \frac{1}{2} \sqrt{1 - \frac{4m_{K}^2}{s_{13}}}. \]  

(14)

For nonresonant processes, the amplitude \( \mathcal{A}(s_{12}, s_{23}, \theta_{j/\phi}) \) is constant over the variables \( s_{12} \) and \( s_{23} \) but has an angular dependence due to the \( J/\psi \) decay. The amplitude is derived from Eq. (5), assuming that the nonresonant \( K^+ K^- \) contribution is a \( S \)-wave (i.e., \( L_R = 0 \), \( L_B = 1 \)) and is uniform in phase space (i.e., \( A_R = 1 \)),

\[ \mathcal{A}(s_{12}, s_{23}, \theta_{j/\phi}) = \frac{P_R}{m_R} \sqrt{\sin^2 \theta_{j/\phi}}. \]  

(15)

**B. Detection efficiency**

The detection efficiency is determined from a phase space simulation sample containing \( 3.4 \times 10^6 \, \overline{B}_s^0 \to J/\psi K^+ K^- \) events with \( J/\psi \to \mu^+ \mu^- \). We also use a separate sample of \( 1.3 \times 10^6 \, \overline{B}_s^0 \to J/\psi \phi \) events. The \( p_T \) and \( p_T \) distributions of the generated \( \overline{B}_s^0 \) mesons are weighted to match the distributions found using \( J/\psi \phi \) data. The simulation is also corrected by weighting for difference between the simulated kaon detection efficiencies and the measured ones determined by using a sample of \( D^{*+} \to \pi^+(D^0 \to K^- \pi^+) \) events.

Next we describe the efficiency in terms of the analysis variables. Both \( s_{12} \) and \( s_{13} \) range from 12.5 GeV\(^2\) to 24.0 GeV\(^2\), where \( s_{13} \) is defined below, and thus are centered at \( s_0 = 18.25 \) GeV\(^2\). We model the detection efficiency using the dimensionless symmetric Dalitz plot observables

\[ x = (s_{12} - s_0)/(1 \text{ GeV}^2), \quad y = (s_{13} - s_0)/(1 \text{ GeV}^2), \]  

(16)

and the angular variable \( \theta_{j/\phi} \). The observables \( s_{12} \) and \( s_{13} \) are related to \( s_{23} \) as

\[ s_{12} + s_{13} + s_{23} = m_R^2 + m_{j/\phi}^2 + m_{K^+ K^-}^2 + m_{K^+ K^-}^2. \]  

(17)

To parametrize this efficiency, we fit the \( \cos \theta_{j/\phi} \) distributions of the \( J/\psi K^+ K^- \) and \( J/\psi \phi \) simulation samples in bins of \( m^2(K^+ K^-) \) with the function

\[ \rho_2(s_{23}, \theta_{j/\phi}) = 1 + \frac{\cos^2 \theta_{j/\phi}}{2 + a \theta_{j/\phi}}, \]  

(18)

giving values of \( a \) as a function of \( m^2(K^+ K^-) \). The resulting distribution, shown in Fig. 7, is described by an exponential function

\[ a(s_{23}) = \exp(a_1 + a_2 s_{23}), \]  

(19)

with \( a_1 = -0.76 \pm 0.18 \) and \( a_2 = (-1.02 \pm 0.15) \text{GeV}^{-2} \). Equation (18) is normalized with respect to \( \cos \theta_{j/\phi} \). The efficiency in \( \cos \theta_{j/\phi} \) depends on \( s_{23} \), and is observed

![FIG. 7 (color online). Exponential fit to the efficiency parameter \( a(s_{23}) \). The point near the \( \phi(1020) \) meson mass is determined more precisely due to the use of a large simulation sample.](image-url)
the polynomial function. The fitted function is shown to be independent of \( s_{12} \). Thus the detection efficiency can be expressed as

\[
e(\alpha, \beta, x, y) = e_1(x, y) \times e_2(\gamma, \delta, x, y). \tag{20}
\]

After integrating over \( \cos \theta_{J/\psi} \), Eq. \( \text{(20)} \) becomes

\[
\int_{-1}^{1} e(\alpha, \beta, x, y) \, d \cos \theta_{J/\psi} = e_1(x, y) \tag{21}
\]

and is modeled by a symmetric fifth-order polynomial function given by

\[
e_1(x, y) = 1 + e_{11} \cos 2 \theta_{KK} \cos \phi + e_{12} \cos 2 \theta_{KK} \sin \phi + e_{13} \sin 2 \theta_{KK} \cos \phi + e_{14} \sin 2 \theta_{KK} \sin \phi + e_{15} \cos \phi + e_{16} \sin \phi,
\]

where \( e_i \) are the fit parameters. The \( P_0^0 \to J/\psi K^+ K^- \) phase space simulation sample is modeled with the polynomial function. The fitted function is shown in Fig. 8, and the projections of the fit are shown in Fig. 9. The efficiency is well described by the parametrization.

For the region within \( \pm 20 \) MeV of the \( \phi(1020) \) mass, the \( \cos \theta_{KK} \) acceptance is used separately, due to the large number of signal events. Here the \( \cos \theta_{KK} \) distribution shows a variation in efficiency, which can be parametrized using the efficiency function

\[
A(\theta_{KK}) = \frac{1 + e_{12} \cos^2 \theta_{KK}}{1 + e_{12}^2/3}, \tag{23}
\]

where the parameter \( e_{12} \) is measured from a fit to the simulated \( J/\psi \phi \) sample with \( e_1(x, y) \times A(\theta_{KK}) \), giving \( e_{12} = -0.099 \pm 0.010 \), as shown in Fig. 10.

The mass resolution is \( \pm 0.7 \) MeV at the \( \phi(1020) \) mass peak, which is added to the fit model by increasing the Breit-Wigner width of the \( \phi(1020) \) to 4.59 MeV.
The shape of the combinatorial background is modeled as

$$C(s_{12}, s_{23}, \theta_{J/\psi}) = \left[ C_1(s_{12}, s_{23}) \frac{PB}{m_B} + \frac{c_0}{(m_0^2 - s_{23})^2 + m_0^2 \Gamma_0^2} \right] \times (1 + \alpha \cos^2 \theta_{J/\psi}),$$

(24)

where $C_1(s_{12}, s_{23})$ is parametrized as

$$C_1(s_{12}, s_{23}) = 1 + c_1(x + y) + c_2(x + y)^2 + c_3 xy + c_4(x + y)^3 + c_5 xy(x + y),$$

(25)

with $c_i, m_0, \Gamma_0$ and $\alpha$ as the fit parameters. The variables $x$ and $y$ are defined in Eq. (16).

Figure 11 shows the mass squared projections from the $B^0_s$ mass sidebands with the fit projections overlaid. The $\chi^2$/ndf of the fit is 291/305. The value of $\alpha$ is determined by fitting the $\cos \theta_{J/\psi}$ distribution of background, as shown in Fig. 12, with a function of the form $1 + \alpha \cos^2 \theta_{J/\psi}$, yielding $\alpha = -0.14 \pm 0.08$.

The reflection background is parametrized as

$$R(s_{12}, s_{23}, \theta_{J/\psi}) = R_1(s_{12}, s_{23}) \times (1 + \beta \cos^2 \theta_{J/\psi}),$$

(26)

where $R_1(s_{12}, s_{23})$ is modeled using the simulation; the projections of $s_{12}$ and $s_{23}$ are shown in Fig. 13. The $J/\psi$ helicity angle dependent part of the reflections is modeled as $1 + \beta \cos^2 \theta_{J/\psi}$, where the parameter $\beta$ is obtained from a fit to the simulated $\cos \theta_{J/\psi}$ distribution, shown in Fig. 14, giving $\beta = -0.19 \pm 0.01$.

FIG. 11 (color online). Invariant mass squared projections of (a) $K^+ K^-$ and (b) $J/\psi K^+$ from the background Dalitz plot of candidates in the $B^0_s$ mass sidebands.

C. Background composition

The shape of the combinatorial background is modeled as

$$C(s_{12}, s_{23}, \theta_{J/\psi}) = \left[ C_1(s_{12}, s_{23}) \frac{PB}{m_B} + \frac{c_0}{(m_0^2 - s_{23})^2 + m_0^2 \Gamma_0^2} \right] \times (1 + \alpha \cos^2 \theta_{J/\psi}),$$

(24)

where $C_1(s_{12}, s_{23})$ is parametrized as

$$C_1(s_{12}, s_{23}) = 1 + c_1(x + y) + c_2(x + y)^2 + c_3 xy + c_4(x + y)^3 + c_5 xy(x + y),$$

(25)

with $c_i, m_0, \Gamma_0$ and $\alpha$ as the fit parameters. The variables $x$ and $y$ are defined in Eq. (16).

Figure 11 shows the mass squared projections from the $B^0_s$ mass sidebands with the fit projections overlaid. The $\chi^2$/ndf of the fit is 291/305. The value of $\alpha$ is determined by fitting the $\cos \theta_{J/\psi}$ distribution of background, as shown in Fig. 12, with a function of the form $1 + \alpha \cos^2 \theta_{J/\psi}$, yielding $\alpha = -0.14 \pm 0.08$.

The reflection background is parametrized as

$$R(s_{12}, s_{23}, \theta_{J/\psi}) = R_1(s_{12}, s_{23}) \times (1 + \beta \cos^2 \theta_{J/\psi}),$$

(26)

where $R_1(s_{12}, s_{23})$ is modeled using the simulation; the projections of $s_{12}$ and $s_{23}$ are shown in Fig. 13. The $J/\psi$ helicity angle dependent part of the reflections is modeled as $1 + \beta \cos^2 \theta_{J/\psi}$, where the parameter $\beta$ is obtained from a fit to the simulated $\cos \theta_{J/\psi}$ distribution, shown in Fig. 14, giving $\beta = -0.19 \pm 0.01$.

FIG. 11 (color online). Invariant mass squared projections of (a) $K^+ K^-$ and (b) $J/\psi K^+$ from the background Dalitz plot of candidates in the $B^0_s$ mass sidebands.

FIG. 12 (color online). Distribution of $\cos \theta_{J/\psi}$ from the background sample fit with the function $1 + \alpha \cos^2 \theta_{J/\psi}$.

FIG. 13. Projections of the reflection background in the variables (a) $m^2(K^+ K^-)$ and (b) $m^2(J/\psi K^+)$, obtained from $B^0 \rightarrow J/\psi K^+(892)$ and $B^0 \rightarrow J/\psi K^0_s(1430)$ simulations.
V. FINAL STATE COMPOSITION

A. Resonance models

The resonances that are likely to contribute are produced from the $s\bar{s}$ system in Fig. 1, and thus are isoscalar ($I = 0$). The $K^+K^-$ system in the decay $B^0_s \rightarrow J/\psi K^+K^-$ can, in principle, have zero or any positive integer angular momentum. Both the $P$-parity and $C$-parity of $K^+K^-$ pair in a state of relative angular momentum $L$ are given by $(−1)^L$.

Therefore the allowed resonances decaying to $K^+K^-$ are limited to $J^{PC} = 0^{++}, 1^{--}, 2^{++}, \ldots$, with isospin $I = 0$. In the kinematically accessible mass range up to 2 GeV, resonances with $J^{PC} = 3^{--}$ or higher are not expected and thus the subsequent analysis only uses spins up to $J = 2$.

Possible resonance candidates are listed in Table I. There could also be a contribution from nonresonant events which we assume to be $S$-wave and evenly distributed over the available phase space.

To study the resonant structures of the decay $B^0_s \rightarrow J/\psi K^+K^-$ we use 20,425 candidates with an invariant mass within ±20 MeV of the observed $B^0_s$ mass peak. This includes both signal and background, with 94% signal purity. We begin our analysis considering only the resonance components $\phi(1020)$, $f_2'(1525)$ and a nonresonant component, established in our earlier measurement [10], and add resonances until no others are found with more than two standard deviation statistical significance ($2\sigma$).

The significance is estimated from the fit fraction divided by its statistical uncertainty. Our best fit model includes a nonresonant component and eight resonance states: $\phi(1020)$, $f_0(980)$, $f_0(1370)$, $f_2'(1525)$, $f_2(1640)$ (|$\lambda| = 1$), $\phi(1680)$ (|$\lambda| = 1$), $f_2(1750)$, and $f_2(1950)$. Most of the resonances considered here are well established except for the modes $f_2(1640)$, $f_2(1750)$, and $f_2(1950)$. Although the existence of $f_2(1640)$ is not confirmed yet [9], the right shoulder of $f_2'(1525)$ fits better when we add this state. The presence of multiple broad overlapping resonances in this region may indicate a failure of the isobar model used in this analysis, but with the present data sample alternative descriptions are not feasible. Indeed, the situation is not clear for the resonance states in the vicinity of 1750 MeV.

The PDG lists a spin-0 resonance, $f_0(1710)$, around 1.72 GeV of $K^+K^-$ invariant mass [9]. The Belle collaboration observed a resonance in the vicinity of 1.75 GeV with $J^{PC} = (\text{even})^{++}$ in their study of $\gamma\gamma \rightarrow K^+K^-$ [28], but could not establish its spin. A state of mass 1767 ± 14 MeV was seen by the L3 collaboration decaying into $K^0SK^0_S$ with $J = 2$ [29]. We find that our data are better fit including the $f_2(1750)$ mode. If we substitute either the $f_0(1710)$ or $f_0(1750)$ resonance the fit is worsened, as the −ln $\mathcal{L}$ increase by 59 and 7 units, respectively.

In the same analysis of $\gamma\gamma \rightarrow K^+K^-$, Belle also observed the $f_2(1950)$ [28] resonance. We include this state in our best fit model. Furthermore, we do not expect significant contributions from the $f_2(1270)$ and $f_0(1500)$ resonances, since the PDG branching fractions are much larger in the $\pi^+\pi^-$ final state than in $K^+K^-$ [9] and we did not see significant contributions from these two resonances in the $B^0_s \rightarrow J/\psi \pi^+\pi^-$ final state [8]. Therefore, these two resonances are not considered in the best fit model. However, we add these states, in turn, to the best fit model in order to test for their possible presence.

The masses and widths of the BW resonances are listed in Table II. When used in the fit they are fixed to the central values, except for the $f_2'(1525)$, whose mass and width are allowed to vary.

The $f_0(980)$ is described by a Flatté resonance shape, see Eq. (12). The parameters describing the function are the mass, and the couplings $g_{\pi\pi}$ and $g_{KK}$, which are fixed in the fit from the previous analysis of $B^0_s \rightarrow J/\psi \pi^+\pi^-$ [8]. The parameters are $m_0 = 939.9 \pm 6.3$ MeV, $g_{\pi\pi} = 199 \pm 30$ MeV and $g_{KK}/g_{\pi\pi} = 3.0 \pm 0.3$. All background and efficiency parameters are fixed in the fit.

To determine the complex amplitudes in a specific model, the data are fitted maximizing the unbinned likelihood given as

$$
\mathcal{L} = \prod_{i=1}^{N} F(s^1_{12}, s^1_{23}, \theta^1_{f/\phi}),
$$

(27)
where \( N \) is the total number of candidates, and \( F \) is the total PDF defined in Eq. (1). The PDF normalization is accomplished by first normalizing the \( J/\psi \) helicity dependent part by analytical integration, and then for the mass dependent part using numerical integration over 400 \( \times \) 800 bins.

The fit determines the relative values of the amplitude strengths, \( \theta^K_\lambda \), and phases, \( \phi^K_\lambda \), defined in Eq. (4). We choose to fix \( \theta^K_0(1020) = 1 \). As only relative phases are physically meaningful, one phase in each helicity grouping must be fixed. In addition, because \( J/\psi K^+ K^- \) is a self-charge-conjugate mode and does not determine the initial \( B \) flavor, the signal function is an average of \( B^0 \) and \( \bar{B}^0 \). If we consider no \( K^+ K^- \) partial-waves of a higher order than \( D \)-wave, then we can express the differential decay rate (\( d\Gamma/dm_{KK}\cos \theta_{KK}\cos \theta_{J/\phi} \)) derived from Eq. (4) in terms of \( S^- \), \( P^- \), and \( D \)-waves including helicity 0 and \( \pm 1 \) components. The differential decay rates for \( B^0 \) and \( \bar{B}^0 \), respectively are

\[
\frac{d\Gamma}{dm_{KK}d\cos \theta_{KK}d\cos \theta_{J/\phi}} = \left| \mathcal{A}^s_{0}\, e^{i\phi^s_0} + \mathcal{A}^s_{p}\, e^{i\phi^s_0} \cos \theta_{KK} + \mathcal{A}^s_{D}\, e^{i\phi^s_0} \left( \frac{3}{2} \cos^2 \theta_{KK} - \frac{1}{2} \right) \right|^2 \sin^2 \theta_{J/\phi} \\
+ \left| \mathcal{A}^s_{p}\, e^{i\phi^s_{p\pm 1}} \left( \frac{1}{2} \sin \theta_{KK} + \mathcal{A}^s_{Dp}\, e^{i\phi^s_{Dp\pm 1}} \frac{5}{2} \sin \theta_{KK} \cos \theta_{KK} \right) \right|^2 = \frac{1 + \cos^2 \theta_{J/\phi}}{2},
\]

and

\[
\frac{d\Gamma}{dm_{KK}d\cos \theta_{KK}d\cos \theta_{J/\phi}} = \left| \mathcal{A}^s_{0}\, e^{i\phi^s_0} - \mathcal{A}^s_{p}\, e^{i\phi^s_0} \cos \theta_{KK} + \mathcal{A}^s_{D}\, e^{i\phi^s_0} \left( \frac{3}{2} \cos^2 \theta_{KK} - \frac{1}{2} \right) \right|^2 \sin^2 \theta_{J/\phi} \\
+ \left| \mathcal{A}^s_{p}\, e^{i\phi^s_{p\pm 1}} \left( \frac{1}{2} \sin \theta_{KK} - \mathcal{A}^s_{Dp}\, e^{i\phi^s_{Dp\pm 1}} \frac{5}{2} \sin \theta_{KK} \cos \theta_{KK} \right) \right|^2 = \frac{1 + \cos^2 \theta_{J/\phi}}{2},
\]

where \( \mathcal{A}^s_\lambda \) and \( \phi^s_\lambda \) are the sum of amplitudes and reference phases, for the spin-\( k \) resonance group, respectively. The decay rate for \( B^0 \) is similar to that of \( \bar{B}^0 \), except \( \theta_{K^+ K^-} \) and \( \theta_{J/\phi} \) are now changed to \( \pi - \theta_{K^+ K^-} \) and \( -\theta_{J/\phi} \) respectively, as a result of using \( K^- \) and \( \mu^- \) to define the helicity angles and hence the signs change in front of the \( \mathcal{A}^s_\lambda \) and \( \mathcal{A}^s_{p\lambda} \) terms.

Summing Eqs. (28) and (29) results in cancellation of the interference involving \( \lambda = 0 \) terms for spin-1, and the \( \lambda = \pm 1 \) terms for spin-2, as they appear with opposite signs for \( B^0 \) and \( \bar{B}^0 \) decays. Therefore we have to fix one phase in the spin-1 (\( \lambda = 0 \)) group (\( \phi^s_0 \)) and one in the spin-2 (\( \lambda = \pm 1 \)) group (\( \phi^s_{Dp} \)). The other phases in each corresponding group are determined relative to that of the fixed resonance.

### B. Fit results

The goodness of fit is calculated from 3D partitions of \( s_{12}, s_{23} \) and \( \cos \theta_{J/\phi} \). We use the Poisson likelihood \( \chi^2 \) [30] defined as

\[
\chi^2 = 2 \sum_{i=1}^{N} \left[ x_i - n_i + n_i \ln \left( \frac{n_i}{x_i} \right) \right]. \tag{30}
\]

</table>
for the $f_2(1750)$ where we allow the $|\lambda| = 1$ component since the $\lambda = 0$ component is significant. For models with one more resonance, the additional components never have more than 2$\sigma$ significance. Figure 15 shows the projection of $m^2(K^+K^-)$ for the best fit model, the $m^2(J/\psi K^+)$ and $\cos \theta_{J/\psi}$ projections are displayed in Fig. 16. The projection of the $K^+K^-$ invariant mass spectrum is shown in Fig. 17.

While a complete description of the $B^0 \rightarrow J/\psi K^+ K^-$ decay is given in terms of the fitted amplitudes and phases, knowledge of the contribution of each component can be summarized by defining a fit fraction, $F^R_\lambda$. To determine $F^R_\lambda$ we integrate the squared amplitude of $R$ over the Dalitz plot. The yield is then normalized by integrating the entire signal function over the same area. Specifically,

$$F^R_\lambda = \frac{\int |d_A^R e^{i\phi_A^R} A^R_\alpha(s_{12}, s_{23}, \theta_{J/\psi}) A^{R*}_\alpha(s_{12}, s_{23}, \theta_{J/\psi}) ds_{12} ds_{23} d\cos \theta_{J/\psi}|^2}{\int S(s_{12}, s_{23}, \theta_{J/\psi}) ds_{12} ds_{23} d\cos \theta_{J/\psi}}.$$ 

(31)

Note that the sum of the fit fractions is not necessarily unity due to the potential presence of interference between two resonances. Interference term fractions are given by

$$\sum_\lambda \left( \sum_R F^R_\lambda + \sum_{R'} F^{RR'}_\lambda \right) = 1.$$ 

(33)

If the Dalitz plot has more destructive interference than constructive interference, the sum of the fit fractions will be greater than unity. Conversely, the sum will be less than one if the Dalitz plot exhibits constructive interference. Note that interference between different spin-$J$ states vanishes because the $d_{J0}$ angular functions in $A^R_\lambda$ are orthogonal.

The determination of the statistical uncertainties of the fit fractions is difficult because they depend on the statistical uncertainty of every fitted magnitude and phase. Therefore we determine the uncertainties from simulated experiments. We perform 500 experiments: each sample is generated according to the model PDF, input parameters are taken from the fit to the data. The correlations of fitted parameters are also taken into account. For each...
experiment the fit fractions are calculated. The distributions of the obtained fit fractions are described by Gaussian functions. The r.m.s. widths of the Gaussian functions are taken as the statistical uncertainties on the corresponding parameters. The fit fractions and phases of the contributing components are given in Table IV, while the fit fractions of the interference terms are quoted in Table V.

**Table VI** shows a comparison of the fit fractions when a different parametrization is used for the $f_0$(980) resonance shape. The BES $f_0$(980) functional form is the same as ours with the parameters $m_0 = 965 \pm 10$ MeV, $g_{\pi\pi} = 165 \pm 18$ MeV and $g_{KK}/g_{\pi\pi} = 4.21 \pm 0.33$ [31]. The BABAR collaboration assumes that the nonresonant $S$-wave is small and consistent with zero [32]. The BABAR functional form is different and parametrized as

$$A_R(s) = \frac{1}{m_R^2 - s + im_R\Gamma_R}\rho_{KK},$$

with $\rho_{KK} = 2P_R/\sqrt{s}$ [33]. The parameters are $m_R = 922 \pm 3$ MeV and $\Gamma_R = 240 \pm 80$ MeV, taken from BABAR’s Dalitz plot analysis of $D^+_s \to K^+ K^- \pi^+$ [33]. The $f_0$(980) fraction is smaller in the BABAR parametrization, while the total $S$-wave fraction is consistent in the three different parameterizations. In all cases, the dominant component is the $\phi$(1020), the second largest contribution is the $f_2^*(1525)$, and the third the $f_0$(980) resonance. There are also significant contributions from the $f_0$(1370), $f_2$(1640), $\phi$(1680), $f_2$(1750), $f_2$(1950) resonances, and nonresonant final states. The amount of $f_0$(980) is strongly parametrization dependent, so we treat these three models separately and do not assign any systematic uncertainty based on the use of these different $f_0$(980) shapes. Therefore we refrain from quoting a branching fraction measurement for the decay $B_s^0 \to J/\psi f_0$(980). The determination of the parameters of the $f_2^*(1525)$ resonance are not dependent on the $f_0$(980) parametrization. The parameters of the $f_2^*(1525)$ are determined to be

$$m_{f_2^*(1525)} = 1522.2 \pm 2.8^{+5.3}_{-2.0} \text{ MeV}, \Gamma_{f_2^*(1525)} = 84 \pm 6^{+10}_{-5} \text{ MeV}.$$

Whenever two or more uncertainties are quoted, the first is the statistical and the second systematic. The latter will be discussed in Section V F. These values are the most accurate determinations of the $f_2^*(1525)$ resonant parameters [9]. Note that our determination of the mass has the same uncertainty as the current PDG average.

**C. $K^+ K^-$ S-wave in the $\phi$(1020) mass region**

It was claimed by Stone and Zhang [12] that in the decay of $B_s^0 \to J/\psi \phi$, the $K^+ K^-$ system can have $S$-wave contributions under the $\phi$(1020) peak of order $7\%$ of the total yield. In order to investigate this possibility we calculate the $S$-wave fractions as given by the fit in 4 MeV mass intervals between $990 < m(K^+K^-) < 1050$ MeV. The resulting behavior is shown in Fig. 18. Here we show the result from our preferred model and also from the alternative $f_0$(980) parametrizations discussed above. The observation of significant $S$-wave fractions in this region means that this contribution must be taken into account when measuring CP violation in the $\phi$ mass region. The total $S$-wave fraction.
We claim that the results are consistent with ours. The D0 collaboration, as shown in Fig. 19, using a time-dependent analysis of the S-wave fraction within the same mass window as a consistent, and more precise (1.1 ± 0.1 ± 0.2)% CDF measured the S-wave fraction as (0.8 ± 0.2)% for $m(K^+K^-)$ within about ±9.5 MeV of the $\phi$ mass [6], while ATLAS quotes (2 ± 2)% for an 11 MeV interval [7]. These results are consistent with ours. The D0 collaboration, however, claimed a (14.7 ± 3.5)% S-wave fraction within approximately ±10 MeV of the $\phi$ meson mass [5], in disagreement with all of the other results.

### TABLE V

Fit fractions matrix for the best fit in units of %. The diagonal elements correspond to the decay fractions in Table IV. The off-diagonal elements give the fit fractions of the interference. The null values originate from the fact that any interference contribution between different spin-$J$ state integrates to zero. Here the resonances are labeled by their masses in MeV and the subscripts denote the helicities.

D. Helicity angle distributions

The decay angular distributions or the helicity angle distributions are already included in the signal model via Eqs. (8) and (9). In order to test the fit model we examine the $\cos \theta_{J/\phi}$ and $\cos \theta_{KK}$ distributions in two different $K^+K^-$ mass regions: one is the $\phi(1020)$ region defined within ±12 MeV of the $\phi(1020)$ mass peak and the other
The experimental mass resolution is not unfolded. The experimental statistical uncertainties are only shown for the LHCb model; they are almost identical for the other cases. The experimental mass resolution is not unfolded.

FIG. 18 (color online). $S$-wave fraction as a function of $m(K^+K^-)$ starting from 990 MeV up to 1050 MeV in 4 MeV mass intervals. The squares (blue), triangles (red), and circles (green) represent the LHCb, BES and BABAR parametrizations of $f_0(980)$, respectively. The experimental statistical uncertainties are only shown for the LHCb model; they are almost identical for the other cases. The experimental mass resolution is not unfolded.

FIG. 19 (color online). $S$-wave fractions in different $m(K^+K^-)$ intervals centered on the $\phi$ meson mass. The squares (blue), triangles (red), and circles (green) represent the LHCb, BES and BABAR parametrizations of $f_0(980)$, respectively. The experimental statistical uncertainties are only shown for the LHCb model; they are almost identical for the other cases. The experimental mass resolution is not unfolded.

FIG. 20 (color online). Background-subtracted efficiency-corrected $\cos \theta_{J/\psi}$ helicity distributions: (a) in $\phi(1020)$ mass region ($\chi^2/\text{ndf} = 54.4/40$), (b) in $f_2(1525)$ mass region ($\chi^2/\text{ndf} = 34.4/40$).

E. Angular moments

The angular moment distributions provide an additional way of visualizing the effects of different resonances and their interferences, similar to a partial wave analysis. This technique has been used in previous studies [8,34].

We define the angular moments $\langle Y_l^m \rangle$ as the efficiency-corrected and background-subtracted $K^+K^-$ invariant mass distributions, weighted by orthogonal and normalized spherical harmonic functions $Y_l^m(\cos \theta_{KK})$, where

$$\langle Y_l^m \rangle = \frac{\int_{-1}^{1} d\Gamma(m_{KK}, \cos \theta_{KK}) Y_l^m(\cos \theta_{KK}) d\cos \theta_{KK}}{\int_{-1}^{1} d\Gamma(m_{KK}, \cos \theta_{KK}) d\cos \theta_{KK}}. \quad (35)$$

If we assume that no $K^+K^-$ partial-waves of a higher order than $D$-wave contribute, then we can express the differential decay rate, derived from Eq. (4) in terms of $S$-, $P$, and $D$-waves including helicity 0 and $\pm 1$ components as

$$\frac{d\tilde{\Gamma}}{dm_{KK}d\cos \theta_{KK}} = 2\pi |S_0 Y_0^0(\cos \theta_{KK}) + P_0 e^{i\Phi_{P_0}} Y_1^0(\cos \theta_{KK}) + D_0 e^{i\Phi_{D_0}} Y_2^0(\cos \theta_{KK})|^2$$

$$+ 2\pi \left|P_{\pm 1} e^{i\Phi_{P_{\pm 1}}} \sqrt{\frac{3}{8\pi}} \sin \theta_{KK} + D_{\pm 1} e^{i\Phi_{D_{\pm 1}}} \sqrt{\frac{15}{8\pi}} \sin \theta_{KK} \cos \theta_{KK}\right|^2, \quad (36)$$

where $S_\lambda$, $P_\lambda$, $D_\lambda$ and $\Phi_{\lambda}$ are real-valued functions of $m_{KK}$, and we have factored out the $S$-wave phase. We can then calculate the angular moments.
FIG. 21 (color online). Background-subtracted efficiency-corrected $\cos \theta_{KK}$ helicity distributions: (a) in $\phi(1020)$ mass region ($\chi^2/\text{ndf} = 57.4/40$), (b) in $f_2(1525)$ mass region ($\chi^2/\text{ndf} = 43.4/40$). The distributions are compatible with expectations for spin-1 and spin-2, respectively.

FIG. 22 (color online). Dependence of the spherical harmonic moments of $\cos \theta_{KK}$ as a function of the $K^+K^-$ mass around the $\phi(1020)$ mass peak after efficiency corrections and background subtraction. The points with error bars are the data and the solid curves are derived from the fit model.
\[
\sqrt{4\pi Y_0^0} = S_0^2 + P_0^2 + D_0^2 + P_{\pm 1}^2 + D_{\pm 1}^2 \\
\sqrt{4\pi Y_1^0} = 2S_0 P_0 \cos \Phi_{P_0} + \frac{4}{\sqrt{5}} P_0 D_0 \cos (\Phi_{P_0} - \Phi_{D_0}) + \frac{8}{\sqrt{5}} P_{\pm 1} D_{\pm 1} \cos (\Phi_{P_{\pm 1}} - \Phi_{D_{\pm 1}}) \\
\sqrt{4\pi Y_2^0} = \frac{2}{\sqrt{5}} P_0^2 + 2S_0 D_0 \cos \Phi_{D_0} + \frac{2\sqrt{5}}{7} D_0^2 - \frac{1}{\sqrt{5}} P_{\pm 1}^2 + \frac{\sqrt{5}}{7} D_{\pm 1}^2 \\
\sqrt{4\pi Y_3^0} = 6\frac{3}{35} P_0 D_0 \cos (\Phi_{P_0} - \Phi_{D_0}) + \frac{6}{\sqrt{35}} P_{\pm 1} D_{\pm 1} \cos (\Phi_{P_{\pm 1}} - \Phi_{D_{\pm 1}}) \\
\sqrt{4\pi Y_4^0} = \frac{6}{7} D_0^2 - \frac{4}{7} D_{\pm 1}^2.
\]

The angular moments for \( l > 4 \) vanish. Figures 22 and 23 show the distributions of the angular moments for the fit model around \( \pm 30 \text{ MeV} \) of the \( \phi(1020) \) mass peak and above the \( \phi(1020) \), respectively. In general the interpretation of these moments is that \( \langle Y_0^0 \rangle \) is the efficiency-corrected and background-subtracted event distribution, \( \langle Y_1^0 \rangle \) the sum of the interference between \( S \)-wave and \( P \)-wave, and \( P \)-wave and \( D \)-wave amplitudes, \( \langle Y_2^0 \rangle \) the

---

FIG. 23 (color online). Dependence of the spherical harmonic moments of \( \cos \theta_{KK} \) as a function of the \( K^+K^- \) mass above 1050 MeV, after efficiency corrections and background subtraction. The points with error bars are the data and the solid curves are derived from the fit model.
sum of $P$-wave, $D$-wave and the interference of $S$-wave and $D$-wave amplitudes, $\langle Y^0 \rangle$ the interference between $P$-wave and $D$-wave amplitudes, and $\langle Y^0 \rangle$ the $D$-wave. As discussed in Sec. VA, the average of $B^0_s$ and $\bar{B}^0_s$ cancels the interference terms that involve $P_0$ and $D_s$. This causes the angular moments $\langle Y^0 \rangle$ and $\langle Y^0 \rangle$ to be zero when averaging over $B^0$ and $\bar{B}^0_s$ decays. We observe that the fit results well describe the moment distributions, except for the $\langle Y^0 \rangle$ and $\langle Y^0 \rangle$ values below 1.2 GeV. This may be the result of statistical fluctuations or imperfect modeling.

### F. Systematic uncertainties

The sources of the systematic uncertainties on the results of the Dalitz plot analysis are summarized in Table VII. The uncertainties due to the background parametrization are estimated by comparing the results from the best fit model with those when the background shape parameters are obtained from a fit to the lower sideband region only. The uncertainties in the efficiency are estimated by comparing the fit results when the efficiency parameters are changed by their statistical uncertainties and are added in quadrature. The effect on the fit fractions of changing the efficiency function is evaluated using a similar method to that used previously [8]. Briefly, we change the efficiency model by increasing the minimum IP $\chi^2$ requirement from 9 to 12.5 on both of the kaon candidates. This has the effect of increasing the $\chi^2$ of the fit to the angular distributions of $B^0_s \to J/\psi \phi$ data by 1 unit. The new efficiency

072004-16
function is then applied to the data with the original minimum IP $\chi^2$ selection of 9, the likelihood is reevaluated and the uncertainties are estimated by comparing the results with the best fit model. The largest variations among these two efficiency categories are included in the uncertainty.

We estimate additional uncertainties by comparing the results when one more resonance is added to the best fit model. The uncertainties due to the line shape of the contributing resonances with fixed mass and width parameters are estimated by varying them individually in the fit according to their combined statistical and systematic uncertainties added in quadrature. We compare the results with the best fit and add them in quadrature to estimate the uncertainties due to the line shape.

Another source of systematic uncertainty is the value we choose for $L_B$, the orbital angular momentum in the $B_s^0$ decay. If $L_R$ equals zero then $L_B$ equals zero. If, however, $L_R$ is 1 then $L_B$ can be either 0 or 1, and if $L_R$ is 2, $L_B$ can be 1, 2 or 3. For our best fit we do not allow multiple values for $L_B$ but choose the lowest allowed value. To estimate the systematic uncertainties due to the choice of $L_B$, we repeat the fit changing the default value of $L_B$, in turn, to each higher allowed value and compare the fit results with the best fit. The differences are grouped into the fit model category, and we assign the largest variations as the systematic uncertainties. These later two categories often give in asymmetric uncertainties.

VI. ABSOLUTE BRANCHING FRACTIONS

Branching fractions are measured from ratios of the decay rates of interest normalized to the well-established $B^-$ decay mode $B^- \rightarrow J/\psi K^-$. This decay mode, in addition to having a well-measured branching fraction, has the advantage of having two muons in the final state and hence the same triggers as the $B_s^0$ decay. However, we require knowledge of the $B_s^0 / B^-$ production ratio. For this we assume isospin invariance and use the $B_s^0 / B^0$ production ratio $f_s/f_d = 0.256 \pm 0.020$, given in Ref. [35]. The branching fractions are calculated using

$$\mathcal{B}(B_s^0 \rightarrow J/\psi X) = \frac{N_{B_s^0}/\epsilon_{B_s^0}}{N_B/\epsilon_B} \times \mathcal{B}(B^- \rightarrow J/\psi K^-) \times \frac{1}{f_s/f_d},$$

where $X$ indicates a specific $K^+K^-$ state, $N$ represents the yield of the decay of interest, and $\epsilon$ corresponds to the overall efficiency. We form an average of $\mathcal{B}(B^- \rightarrow J/\psi K^-) = (10.18 \pm 0.42) \times 10^{-4}$ using the recent Belle [36] and BABAR [37] measurements, corrected to take into account different rates of $B^+B^-$ and $B_s^0B_s^0$ pair production from $Y(4S)$ using

$$\frac{\Gamma(B^+B^-)}{\Gamma(B_s^0B_s^0)} = 1.055 \pm 0.025 [9].$$

The detection efficiency is obtained from simulation and is a product of the geometrical acceptance of the detector, the combined reconstruction and selection efficiency, and is a product of the geometrical acceptance of the detector, the combined reconstruction and selection efficiency. The detection efficiencies and their uncertainties due to the line shape.

Another source of systematic uncertainty is the value we choose for $L_B$, the orbital angular momentum in the $B_s^0$ decay. If $L_R$ equals zero then $L_B$ equals zero. If, however, $L_R$ is 1 then $L_B$ can be either 0 or 1, and if $L_R$ is 2, $L_B$ can be 1, 2 or 3. For our best fit we do not allow multiple values for $L_B$ but choose the lowest allowed value. To estimate the systematic uncertainties due to the choice of $L_B$, we repeat the fit changing the default value of $L_B$, in turn, to each higher allowed value and compare the fit results with the best fit. The differences are grouped into the fit model category, and we assign the largest variations as the systematic uncertainties. These later two categories often give in asymmetric uncertainties.

VI. ABSOLUTE BRANCHING FRACTIONS

Branching fractions are measured from ratios of the decay rates of interest normalized to the well-established decay mode $B^- \rightarrow J/\psi K^-$. This decay mode, in addition to having a well-measured branching fraction, has the advantage of having two muons in the final state and hence the same triggers as the $B_s^0$ decay. However, we require knowledge of the $B_s^0 / B^-$ production ratio. For this we assume isospin invariance and use the $B_s^0 / B^0$ production ratio $f_s/f_d = 0.256 \pm 0.020$, given in Ref. [35]. The branching fractions are calculated using

$$\mathcal{B}(B_s^0 \rightarrow J/\psi X) = \frac{N_{B_s^0}/\epsilon_{B_s^0}}{N_B/\epsilon_B} \times \mathcal{B}(B^- \rightarrow J/\psi K^-) \times \frac{1}{f_s/f_d},$$

where $X$ indicates a specific $K^+K^-$ state, $N$ represents the yield of the decay of interest, and $\epsilon$ corresponds to the overall efficiency. We form an average of $\mathcal{B}(B^- \rightarrow J/\psi K^-) = (10.18 \pm 0.42) \times 10^{-4}$ using the recent Belle [36] and BABAR [37] measurements, corrected to take into account different rates of $B^+B^-$ and $B_s^0B_s^0$ pair production from $Y(4S)$ using

$$\frac{\Gamma(B^+B^-)}{\Gamma(B_s^0B_s^0)} = 1.055 \pm 0.025 [9].$$

The detection efficiency is obtained from simulation and is a product of the geometrical acceptance of the detector, the combined reconstruction and selection efficiency and the trigger efficiency. The efficiency also includes the efficiency of the Dalitz plot model for the case of $B_s^0 \rightarrow J/\psi K^+K^-$, where the best fit model is used. The detection efficiencies and their various correction factors are given in Table VIII.

Contributions from Dalitz analysis

- Efficiency: 3.1
- Background: 0.0
- Fit model: $+0.7$
- Sum in quadrature of items above: 5.0
- $f_s/f_d$: 7.8

where the branching fractions $\mathcal{B}(\phi(1020) \rightarrow K^+ K^-) = (48.9 \pm 0.5\%)$ and $\mathcal{B}(f'_2(1525) \rightarrow K^+ K^-) = (44.4 \pm 1.1\%)$ are used [9]. Here the first uncertainty in each case is statistical, the second is systematic and the third reflects the uncertainty due to $f_s/f_d$. Note that these are the time-integrated branching fractions. Results on the polarization fractions of $\overline{B}^0 \rightarrow J/\psi \phi(1020)$ from a time-dependent analysis will be forthcoming in a separate publication [38]. The ratio of $\mathcal{B}(\overline{B}^0 \rightarrow J/\psi f'_2(1525))/\mathcal{B}(\overline{B}^0 \rightarrow J/\psi \phi(1020))$ is consistent with our previous result [10], D0 [11], and the Belle result [39]. The current PDG value of $\mathcal{B}(\overline{B}^0 \rightarrow J/\psi \phi(1020)) = (1.4 \pm 0.5) \times 10^{-3}$ is dominated by the CDF measurement [40]. Our measured value is in good agreement with this measurement and also the most recent yet unpublished values measured by CDF [41] and Belle [39]. The Belle collaboration has also recently reported the branching fraction of $\mathcal{B}(\overline{B}^0 \rightarrow J/\psi K^+ K^-)$ [39], where $\overline{B}^0 \rightarrow J/\psi \phi(1020)$ is excluded.

The systematic uncertainty on the branching fraction has several contributions listed in Table IX. Since the branching fractions are measured with respect to $B^- \rightarrow J/\psi K^-$ which has a different number of charged tracks than the decays of interest, a 1% systematic uncertainty is assigned due to differences in the tracking performance between data and simulation. Another 2% uncertainty is assigned for the additional kaon which is due to decay in flight, large multiple scatterings and hadronic interactions along the track. Using the PDG value for the $\overline{B}^0$ lifetime [9] as input gives rise to an additional 1.5% systematic uncertainty. Small uncertainties are introduced if the simulation does not have the correct $B$ meson kinematic distributions. We are relatively insensitive to any of these differences in the $B$ meson $p$ and $p_T$ distributions since we are measuring the relative rates. By varying the $p$ and $p_T$ distributions we see at most a change of 0.5%. There is a 1% systematic uncertainty assigned for the relative particle identification efficiencies. An uncertainty of 0.02% is included due to the change of the efficiency function Eq. (20). Three additional uncertainties are considered in the branching fractions of $\mathcal{B}(\overline{B}^0 \rightarrow J/\psi \phi(1020))$ and $\mathcal{B}(\overline{B}^0 \rightarrow J/\psi f'_2(1525))$ as these are measured from the fit fractions of the Dalitz plot analysis. The total systematic uncertainty is obtained by adding each source of systematic uncertainty in quadrature as they are uncorrelated.

VII. CONCLUSIONS

We have determined the final state composition of the $\overline{B}^0 \rightarrow J/\psi K^+ K^-$ decay channel using a modified Dalitz plot analysis where we include the decay angle of the $J/\psi$. The largest contribution is the $\phi(1020)$ resonance, along with other $S$-, $P$- and $D$-wave $K^+ K^-$ states, and a non-resonant $K^+ K^-$ contribution. All of the components are listed in Table IV. The mass and width of the $f'_2(1525)$ resonance are measured as

$$m_{f'_2(1525)} = 1522.2 \pm 2.8^{+5.3}_{-3.0} \text{ MeV},$$
$$\Gamma_{f'_2(1525)} = 84 \pm 6^{+10}_{-5} \text{ MeV}.$$

We also observe a significant $S$-wave component that is present over the entire $K^+ K^-$ mass region. Within $\pm 12$ MeV of the $\phi(1020)$ mass it is $(1.1 \pm 0.1^{+0.2}_{-0.1})\%$ of the yield, and can affect precision $CP$ violation measurements [12]. Finally we determine the absolute branching fractions.
\( \mathcal{B}(B_s^0 \to J/\psi K^+ K^-) = (7.70 \pm 0.08 \pm 0.39 \pm 0.60) \times 10^{-4}, \)
\( \mathcal{B}(B_s^0 \to J/\psi \phi(1020)) = (10.50 \pm 0.13 \pm 0.64 \pm 0.82) \times 10^{-4}, \)
\( \mathcal{B}(B_s^0 \to J/\psi f_2^0(1525)) = (2.61 \pm 0.20^{+0.32}_{-0.46} \pm 0.20) \times 10^{-4}, \)

where the first uncertainty in each case is statistical, the second is systematic and the third due to \( f_s/f_d \). These results provide a good understanding of the \( J/\psi K^+ K^- \) final state in \( B_s^0 \) decays over the entire kinematically allowed region. The \( J/\psi f_2^0(1525) \) results supersede those of Ref. [10]. This decay mode offers the opportunity for additional measurements of \( CP \) violation [42].

**ACKNOWLEDGMENTS**

We express our gratitude to our colleagues in the CERN accelerator departments for the excellent performance of the LHC. We thank the technical and administrative staff at the LHCb institutes. We acknowledge support from CERN and from the national agencies: CAPES, CNPq, FAPERJ and FINEP (Brazil); NSFC (China); CNRS/IN2P3 and Region Auvergne (France); BMBF, DFG, HGF and MPG (Germany); SFI (Ireland); INFN (Italy); FOM and NWO (Netherlands); ANCS/IFA (Romania); MinES, Rosatom, RFBR and NRC “Kurchatov Institute” (Russia); BMBF, DFG and GENCAT (Spain); SNSF and SER (Switzerland); NAS Ukraine (Ukraine); STFC (United Kingdom); NSF (USA). We also acknowledge the support received from the ERC under FP7. The Tier1 computing centers are supported by IN2P3 (France), KIT and BMBF (Germany), INFN (Italy), NWO and SURF (Netherlands), PIC (Spain), GridPP (United Kingdom).

We are thankful for the computing resources put at our disposal by Yandex LLC (Russia), as well as to the communities behind the multiple open source software packages that we depend on.
