Abstract

Ribonucleotide reductase (RNR) catalyzes the reduction of ribonucleotides to deoxyribonucleotides. Class I RNRs are composed of two homodimeric proteins, \(\alpha\)2 and \(\beta\)2. The class Ia \(E.\ coli\) \(\beta\)2 contains dinuclear, antiferromagnetically coupled iron centers and one tyrosyl free radical, \(Y_{122}\)\(^•\)/\(\beta\)2. \(Y_{122}\)\(^•\) acts as a radical initiator in catalysis. Redox-linked conformational changes may accompany \(Y_{122}\) oxidation and provide local control of proton-coupled electron transfer reactions. To test for such redox-linked structural changes, FT-IR spectroscopy was employed in this work. Reaction-induced difference spectra, associated with the reduction of \(Y_{122}\) by hydroxyurea, were acquired from natural abundance, \(\text{H}_2\)\(^4\) tyrosine, and \(\text{H}^{15}\)\(^N\) tyrosine labeled \(\beta\)2 samples. Isotopic labeling led to the assignment of a 1514 cm\(^{−1}\) band to the \(\nu_{19a}\) ring stretching vibration of \(Y_{122}\) and of a 1498 cm\(^{−1}\) band to the \(\nu_{7a}\) CO stretching vibration of \(Y_{122}\)\(^•\). The reaction-induced spectra also exhibited amide I bands, at 1661 and 1652 cm\(^{−1}\). A similar set of amide I bands, with frequencies of 1675 and 1651 cm\(^{−1}\), was observed when \(Y\)\(^•\) was generated by photolysis in a pentapeptide, which matched the primary sequence surrounding \(Y_{122}\). This result suggests that reduction of \(Y_{122}\)\(^•\) is linked with structural changes at nearby amide bonds and that this perturbation is mediated by the primary sequence. To explain these data, we propose that a structural perturbation of the amide bond is driven by redox-linked electrostatic changes in the tyrosyl radical aromatic ring.
In previous work, high resolution magnetic resonance studies of Y122 were performed. Comparison with the X-ray structure of reduced β2 suggested that a Cα-Cβ single bond rotation may occur when Y122 is oxidized. This single bond rotation was attributed to an electrostatic repulsion between Asp-84 and Y122 and would disconnect Y122 from the hydrogen bond network at the diiron site. A Y• conformational rearrangement has also been proposed to occur with Y oxidation in pentapeptides and tyrosinate at 85 K.

To identify redox-linked structural changes associated with electron transfer reactions in β2, we have performed FT-IR spectroscopy on the purified E. coli subunit in 2H2O buffer (Supplemental information, Figs. S1 and S2). FT-IR spectroscopy has emerged as a powerful tool in elucidating enzyme mechanisms {reviewed in ref 18}. This approach has been used to study redox-active tyrosines in other proteins, such as photosystem II19 and cytochrome c oxidase.20

The reaction-induced difference spectrum, associated with the reduction of Y122•, is presented in Figs. 1A and 2A. These data were acquired by one electron reduction of Y122• with hydroxyurea21–24 over 10 min. Based on the rate constant in 2H2O (Figs. S3 and S4), an estimated ~60% of Y122• is reduced during the 10 min FT-IR measurement.

In the difference spectrum shown in Fig. 1A, unique bands of tyrosyl radical, Y122•, will be positive features; unique bands of Y122 will be negative features. Using model compounds and DFT calculations, it has been shown that oxidation of tyrosine leads to an upshift of the CO stretching vibration to 1516 cm\(^{-1}\) (\(\nu_7a\)) and to perturbations of the aromatic ring stretching frequencies, at ~1600 (\(\nu_8a\)) and ~1500 (\(\nu_{19a}\)) cm\(^{-1}\) (Figs. 1A and 2A and see ref 25 and refs therein). Oxidation of the tyrosine aromatic side chain in peptides and in tyrosinate at pH 11 gave similar results for the CO and \(\nu_{19a}\) ring stretching modes {Fig. 1D and E and refs 17, 26}. Previous Raman studies of the E. coli and mouse β2 subunits have attributed bands at 1498\(^{27}\) and 1515\(^{28}\) cm\(^{-1}\), respectively, to the CO vibration.

To identify Y122•/Y122 contributions to the natural abundance spectrum (Figs. 1A and 2A), the β2 subunit was labeled with the 2H4-tyrosine isotopomer (Figs. 1B and 2B). 2H4 tyrosine labeling resulted in a downshift of a negative band at 1514 cm\(^{-1}\) (\(\nu_7a\)) and to perturbations of the aromatic ring stretching frequencies, at ~1600 (\(\nu_8a\)) and ~1500 (\(\nu_{19a}\)) cm\(^{-1}\) (Figs. 2A and B). This band was not observed in a negative Metβ2 control (Fig. 1F) or in a negative control, in which the β2 subunit was mixed with buffer instead of hydroxyurea (Fig. 1G). Based on previous model compound studies and DFT calculations\(^{25}\), we assign this band to a ring stretching vibration (\(\nu_{19a}\)) of Y122. From DFT calculations, the expected isotope-induced downshift is 80 cm\(^{-1}\).\(^{25}\)

2H4 labeling also resulted in a downshift of a positive band at 1498 cm\(^{-1}\) to 1480 cm\(^{-1}\) (Figs. 2A and B). This band was not observed in the negative controls (Figs. 1F or G) and is assigned to the CO stretching vibration (\(\nu_7a\)) of Y122•. From DFT calculations, the expected isotope-induced downshift is ~20 cm\(^{-1}\).\(^{25}\) The assignment of the 1498 cm\(^{-1}\) band is in agreement with previous Raman studies.\(^{27}\)

These data establish that the CO vibrational band of Y122• is downshifted ~20 cm\(^{-1}\) from its frequency in Y• model compounds,\(^{17, 25}\) where it is observed as a positive band at 1516 cm\(^{-1}\) (Fig. 1D and E). The symmetric ring stretching mode, \(\nu_8a\), at negative 1605 cm\(^{-1}\) (Fig. 1E) was not observed when Y• is generated in the pentapeptide (Fig. 1D) or in β2 (Fig. 1A).

In addition to bands associated with tyrosine oxidation, the reaction-induced spectrum in Fig. 1A reveals coupled, oxidation-induced effects on the protein environment. For example, Fig. 1A exhibits a negative band at 1661 cm\(^{-1}\) and a positive band at 1652 cm\(^{-1}\). This is a
spectral region characteristic of amide I C=O vibrational bands. These data suggest that Y122• reduction is coupled with a structural change in the β2 subunit.

As a first step in interpretation of the amide I spectral contributions, we studied a pentapeptide, RSYTH, matching the sequence containing Y122 in the β2 subunit. The pentapeptide spectrum in 2H2O buffer (Fig. 1D) exhibited several bands in the amide I region, at 1675 and 1651 cm⁻¹, which were not observed when tyrosyl radical was generated in a powder tyrosinate sample (Fig. 1E). This result suggests that electron transfer reactions are linked with a structural change in one or more peptide bonds in the pentapaptide and in the β2 sample. Because the pentapeptide is expected to have no defined structure in solution, the primary sequence must mediate this redox-linked interaction. We propose that this conformational change occurs at adjacent peptide bonds to Y122•.

15N-labeling of tyrosine in β2 was employed (Fig. 1C and 2C) to test if the structural perturbation occurs at the S121-Y122 amide bond. The effect of 15N labeling is expected to be detectable [for example, see ref 30], because the amide I normal mode involves nitrogen displacement. However, 15N labeling had no significant effect on the reaction-induced spectrum (Figs. 2A and C). This result is consistent with the conclusion that the redox-linked structural change does not perturb the Ser-Tyr amide linkage, but other amide bonds near Y122.

We hypothesize that the structural perturbation of the amide bond in the β2 and the pentapeptide samples is driven by an electrostatic change. Electrostatic maps predict a change in aromatic ring charge distribution. An oxidation-induced change in charge distribution will lead to alterations in the C-N bond ionic character, planarity, and force constant through a Stark effect. This interpretation is congruent with recent ESEEM studies of pentapeptide samples, which have shown sequence-dependent changes in nuclear quadrupole interactions in tyrosyl radicals.

Redox-linked structural changes at Y122/Y122• may partially control PCET reactions during the RNR reaction cycle. These conformational alterations are likely to cause changes in Y122 interactions with its hydrogen bonding partner. Therefore, these structural changes may play a role in regulation of Y122 midpoint potential and its reversible protonation/deprotonation reactions. This work provides spectroscopic evidence for dynamic structural changes in RNR.

Figure 1.
Reaction-induced FT-IR spectra, monitoring redox-linked structural changes induced by Y122• reduction with 50 mM hydroxyurea. Spectra (A-C, F and G) were acquired at 20°C in $^2$H$_2$O buffer. In (A), the (250 μM) β2 sample was natural abundance, in (B) $^2$H$_4$-tyrosine labeled, and in (C) $^{15}$N-tyrosine labeled. In (D) and (E), Y• was generated using 266 nm photolysis at 80 K in the RSTYH peptide (D) or in tyrosinate (E) at $p^2$H 11. (F) is a (250 μM) Metβ2 control difference spectrum, which lacks Y122•, but was mixed with hydroxyurea. (G) is a (250 μM) β2 control difference spectrum, in which β2 was mixed with buffer, instead of hydroxyurea. The difference spectra were constructed: Y•-minus-Y. The spectra are averages from 8 (A), 6 (B), 8 (C), 5 (D), 3 (E), 6 (F), and 11 (G) samples.
