Measurement of the inelastic proton–proton cross-section at $\sqrt{s} = 7$ TeV with the ATLAS detector

The ATLAS Collaboration

The dependence of the rate of proton–proton interactions on the centre-of-mass collision energy, $\sqrt{s}$, is of fundamental importance for both hadron collider physics and particle astrophysics. The dependence cannot yet be calculated from first principles; therefore, experimental measurements are needed. Here we present the first measurement of the inelastic proton–proton interaction cross-section at a centre-of-mass energy, $\sqrt{s}$, of 7 TeV using the ATLAS detector at the Large Hadron Collider. Events are selected by requiring hits on scintillation counters mounted in the forward region of the detector. An inelastic cross-section of $60.3 \pm 2.1 \text{mb}$ is measured for $\xi > 5 \times 10^{-6}$, where $\xi$ is calculated from the invariant mass, $M_{XX}$, of hadrons selected using the largest rapidity gap in the event. For diffractive events, this corresponds to requiring at least one of the dissociation masses to be larger than 15.7 GeV.
Since the earliest days of particle physics, measurements of the total pp and $pp$ cross-sections and their theoretical understanding have been topics of much interest. The cross-sections cannot yet be calculated by quantum chromodynamics, and many approaches have been used to describe the existing measurements. General arguments based on unitarity and analyticity imply a bound (the Froissart bound\(^{23}\)) on the high-energy behaviour of total hadronic cross-sections. This bound is independent of the details of the strong interaction dynamics and states that the total cross-section cannot rise faster than $\ln(s)$, where $s$ is the centre-of-mass energy. Recently, it has been extended to the inelastic cross-section\(^1\). Existing experimental data\(^1\) show a rise in the hadronic cross-sections with $s$, but it is unclear whether the asymptotic behaviour has already been reached. In this letter, a direct measurement of the inelastic $p$-air cross-section in the multi-TeV regime are available from cosmic-ray shower detection experiments\(^{24}\), and have been used to infer the $pp$ cross-section albeit with significant uncertainties. The measurement presented here is of direct relevance for the modelling of high energy cosmic ray showers.

The most common models that describe the data up to $\sqrt{s} = 1.8$ TeV predict a rise of the total cross-section with a simple power law ($\sigma(0) \propto s^{0.1}$, where $\sigma(0)$ denotes the Pomeron-trajectory intercept)\(^{3,14}\) or with a power law depending on $\ln(s)$ (refs 12–16). Others employ quantum chromodynamics for aspects of the calculation\(^{17–20}\). However, although the phenomenological description of the existing data is largely adequate, there are significant uncertainties on the extrapolation to higher energies, partly due to a long-standing $2.7\sigma$ discrepancy between the two highest energy collider measurements of the total $pp$ cross-section by CDLM\(^{21}\) and E811 (ref. 22).

The inelastic $pp$ cross-section at $\sqrt{s} = 7$ TeV is measured with data taken by the ATLAS experiment\(^{23}\) at the Large Hadron Collider (LHC)\(^{24}\). The data considered were collected during a single 8-hour fill beginning 31 March 2010, corresponding to an integrated luminosity of $20.3 \pm 0.7 \mu\text{b}^{-1}$ and a peak instantaneous luminosity of $1.2 \times 10^{27} \text{cm}^{-2}\text{s}^{-1}$. The mean number of interactions per crossing in this fill is $0.01$. The analysis uses highly efficient scintillation counters, the minimum bias trigger scintillator (MBTS) detectors, to detect inelastic collisions. They are insensitive to diffractive dissociation processes in which the dissociation systems have small invariant masses, $M_\text{NN}$. Their acceptance corresponds approximately to $\xi = M_\text{NN}/s > 5 \times 10^{-4}$, equivalent to $M_\text{NN} > 15.7 \text{GeV}$ for $\sqrt{s} = 7$ TeV. The cross-section measurement presented here is restricted to this kinematic range. However, to compare the data with previous measurements, an extrapolation of the cross-section is performed to the full $\xi$ range, $\xi > m_\text{tr}/s$ where $m_\text{tr}$ is the proton mass.

**Results**

Acceptance determination. Monte Carlo (MC) simulations are used to determine the acceptance of the event selection and to assess systematic uncertainties. The detector response to the generated events is simulated using the ATLAS simulation\(^{25}\) based on Geant4 (ref. 26), and both the simulated and data events are reconstructed and analysed with the same software. The Pythia6 (ref. 27), Pythia8 (ref. 28) and Phojet\(^{29,30}\) generators are used to predict properties of inelastic collisions. These generators distinguish between different processes that contribute to inelastic $pp$ interactions: single dissociative (SD) processes, $pp \rightarrow ppX$, in which one proton dissociates; double dissociative (DD) processes, $pp \rightarrow AX$, in which both protons dissociate with no net colour flow between the systems X and Y; and non-diffractive (ND) processes in which colour flow is present between the two initial-state protons. The model by Schuler and Sjöstrand\(^{31}\), used by Pythia6 and Pythia8, predicts cross-sections of 48.5, 13.7 and 9.3 mb for the ND, SD and DD processes, respectively. Whereas the cross-sections used by Pythia6 and Pythia8 are identical, they differ in the modelling of the hadronic final state. Phojet predicts the corresponding cross-sections as 61.6 mb (ND), 10.7 mb (SD) and 3.9 mb (DD). Because of differences in implementation of the interface between large $\xi$ diffractive (SD and DD) processes and ND processes in Pythia and Phojet, the fractional contribution of these processes is a model-dependent quantity. Phojet also includes a 1.1 mb contribution from central diffraction (CD), $pp \rightarrow ppX$, a process not implemented in Pythia, wherein neither proton dissociates, but the Pomeron–trajectory exchange results in energy loss for the protons and the production of a central system of particles. The MC generators define the inelastic cross-section as the sum of these contributions, and thus Schuler and Sjöstrand (Phojet) predicts an inelastic cross-section of 71.5 mb (77.3 mb). Other recent predictions for this cross-section at $\sqrt{s} = 7$ TeV are 69 mb (ref. 15), 65–67 mb (ref. 17) and personal communication with the author), 68 mb (refs 18,19) and 60–75 mb (ref. 20).

Although the cross-section measured here is quoted for a restricted $\xi$ range, $\xi$ is not directly measured. However, the $\eta$ coverage of the MBTS implies a lower bound on the range of $\xi$-values for events that the detectors can observe. To study the acceptance as a function of $\xi$, MC generators are used. The variable $\xi$ is defined at the particle level by dividing the final state particles from the MC generators into two systems, X and Y. The mean $\eta$ of the two particles separated by the largest pseudorapidity gap in the event is used to assign all particles with greater pseudorapidity to one system and all particles with smaller pseudorapidity to the other\(^2\). The mass, $M_{\text{XY}}$, of each system is calculated, and the higher mass system is defined as X while the lower mass system is defined as Y. In the case of SD, Y is the non-dissociated proton. The variable $\xi$ is then given by $\xi = M_{\text{XY}}/s$ and it is bounded by the elastic limit, satisfying $\xi > m_\text{tr}/s$. As expected from kinematic considerations, a strong correlation is observed, independently of the MC model used to determine $\xi$, between $\xi$ and the pseudorapidity of the hadron from X that is farthest from the initial-state proton pseudorapidity. Therefore, the upper limit of the MBTS detector acceptance of $|\eta| < 3.84$ (see Methods) can be translated into a limit on the $\xi$ of observed events. Thus the measurement is restricted in its $\xi$ range; there is no requirement on $M_\text{NN}$. Several models are used for the dependence of the diffractive cross-sections on $\xi$. The Schuler and Sjöstrand model has a relatively flat dependence on $\xi$, whereas the Phojet model predicts a slight decrease with decreasing $\xi$. Pythia8 has several extra predictions for the $\xi$-dependence of the diffractive cross-sections that are considered. In the low $\xi$ regime, Bruni and Ingelman\(^3\) predict a flat $\xi$ dependence whereas Donnachie and Landshoff (DL)\(^3\) and Berger et al.\(^3\) predict

$$\frac{d\sigma_{\text{DD}}}{d\xi} \propto \frac{1}{\xi^{1+\varepsilon}}$$

where $\varepsilon = \alpha(0) - 1$. Values of $\varepsilon$ between 0.06 and 0.10, and of $\alpha'$ between 0.10 and 0.40 GeV\(^{-2}\) are considered for the DL model. $\alpha'$ is the slope of the Pomeron trajectory that is assumed to be linear such that $\sigma(t) = \sigma(0) + \alpha't$. The DL model with $\varepsilon = 0.085$ and $\alpha' = 0.25$ GeV\(^{-2}\) with Pythia8 fragmentation is the default model in this analysis, and the other models are used to assess uncertainties in the modelling of diffractive events.

Cross-section calculation elements. Experimentally the cross-section is calculated using

$$\sigma_{\text{inel}}(\xi > 5 \times 10^{-4}) = \frac{(N - N_{NC})}{N_{MC}} \times \int dt \times \frac{1 - f_{\xi < 5 \times 10^{-4}}}{\epsilon_{\text{inel}}}$$

where $N$ is the number of selected events, $N_{NC}$ is the number of background events, $f_{\xi < 5 \times 10^{-4}}$ is the fraction of events that pass the event.
selection but have $\xi < 5 \times 10^{-6}$, $\int \Delta t$ is the integrated luminosity, and $\epsilon_{\text{sel}}$ and $\epsilon_{\text{inst}}$ are the trigger and offline event selection efficiencies in the selected $\xi$-range. For $\xi = 5 \times 10^{-6}$, $\epsilon_{\text{inst}}$ is 50%, rising to nearly 100% for $\xi > 10^{-5}$. The dependence of the efficiency on $\xi$ is similar for the SD and DD processes and for different MC generators. The measurement is quoted for $\xi > 5 \times 10^{-6}$ that gives the smallest correction factor, $(1 - f_{\xi < 5 \times 10^{-6}})/\epsilon_{\text{inst}}$, and thus yields the smallest systematic uncertainty on the measurement due to the underlying $\xi$-distribution.

In this measurement, $N_{\text{incl}}$ and $\epsilon_{\text{inst}}$ are determined directly from the data. The MBTS individual counter efficiencies in the MC simulation are tuned to match the observed efficiencies in data. Then $\epsilon_{\text{inst}}$ and $f_{\xi < 5 \times 10^{-6}}$ are taken from the tuned MC simulation. To reduce the uncertainties in the factors taken from MC simulation, the relative diffractive dissociation cross-section, $f_{\text{D}} = (\sigma_{\text{D}} + \sigma_{\text{SD}} + \sigma_{\text{DI}})/\sigma_{\text{inst}}$, for each generator is constrained. Each of these steps is described in detail below.

The MBTS functions as a trigger by determining the number of scintillation counters with a signal passing a leading-edge discriminator; in this analysis, at least one trigger signal must be present. In the offline reconstruction, the MBTS signals are fit to obtain the total charge and timing of the signal. The offline event selection requires at least two counters with a charge larger than 0.15 pC. This threshold is set to be well above the noise level, which is well described by a Gaussian centred at zero with width 0.02 pC. This inclusive sample contains 1,220,743 data events. To constrain the diffractive components, a subset of events that have at least two hits on one side of the MBTS detector and no hits on the opposing side (in z) are selected. In the data, 122,490 of these single-sided events are observed.

**Backgrounds.** Backgrounds arise from beam-related interactions, such as collisions of the beam with gas particles in the beam-pipe or with material upstream from the detector, and slowly-decaying, collision-induced radiation termed ‘afterglow’ 

Additionally, instrumental noise and cosmic rays provide backgrounds that were studied and found to be negligible for this analysis. The beam-related backgrounds are determined using the number of selected events collected in this fill with the non-colliding bunches, that is, the single-sided ratio between 0 and 1. The resulting value using the default DL uncertainty on the data when varying the double- to single-dissociation fraction of the ND process pass the single-sided event selection, less than 1% of the ND process are observed.

The MBTS individual counter efficiencies in the MC simulation are tuned to match the observed efficiencies in data. Then $\epsilon_{\text{inst}}$ and $f_{\xi < 5 \times 10^{-6}}$ are taken from the tuned MC simulation. To reduce the uncertainties in the factors taken from MC simulation, the relative diffractive dissociation cross-section, $f_{\text{D}} = (\sigma_{\text{D}} + \sigma_{\text{SD}} + \sigma_{\text{DI}})/\sigma_{\text{inst}}$, for each generator is constrained. Each of these steps is described in detail below.

**Detector efficiency and modelling.** The trigger efficiency of the MBTS detector, with respect to the offline requirement, $\epsilon_{\text{inst}}$ is measured to be 99.96$^{+0.05}_{-0.06}$ (statistical errors) using events triggered randomly on colliding beams. The systematic uncertainty on $\epsilon_{\text{inst}}$ is determined using a second, independent trigger as reference. The difference between the two efficiency determinations leads to a 0.1% uncertainty on the cross-section measurement.

The data and MC simulation agreement in the MBTS counter response is checked using other detector subsystems with overlapping $\eta$ ranges: charged particles reconstructed by the tracking detector (2.09 < $|\eta|$ < 2.5), and calorimeter showers in the inner wheel of the electromagnetic calorimeter (2.5 < $|\eta|$ < 3.2) and in the forward calorimeter (3.1 < $|\eta|$ < 3.84). The efficiency with respect to a track (calorimeter energy deposit) to have a signal above the 0.15 pC threshold in the outer (inner) counters is on average 98.5% (97.5%) for the data and a constant 99.4% (98.7%) in the MC simulation. The individual counter efficiencies deviate by up to 2.0% (2.5%) from the average in the data. The MC simulation is corrected to match the data efficiency, and the maximum variations in the counter responses are considered as a systematic uncertainty. This results in a 0.1% uncertainty on the cross-section measurement.

The offline selection efficiency, $\epsilon_{\text{off}}$, depends on the amount of material traversed by particles before hitting the MBTS detector. The rate of photons (primarily from $\pi^0$ decays) converting to electrons that are subsequently detected by the MBTS increases with extra material, resulting in an increase of $\epsilon_{\text{off}}$. Second order effects arise from charged particles scattering out of the MBTS acceptance region (decreasing $\epsilon_{\text{off}}$), or charged particles scattering into the acceptance region (increasing $f_{\xi < 5 \times 10^{-6}}$). Within the tracking volume ($|\eta| < 2.5$), the material distribution has been used studying conversion electrons and $K^0_S \rightarrow \pi^+\pi^-\pi^0$ decays, and is known to better than ±5% in the central region of the detector and to ±10% for 2.2 < $|\eta|$ < 2.5 (ref. 38). In the region $|\eta| > 2.5$, the material is dominated by the cooling and electrical services to the silicon pixel detector, and an uncertainty of ±40% is assumed. This is validated in-situ using the fraction of events wherein we observe significant energy in the forward calorimeters but no signal (above noise) in the MBTS detector. The resulting systematic uncertainty on the cross-section is 0.2%.

Misalignments of the MBTS detector with respect to the nominal centre of the detector could change the event selection efficiency for a particular value of $\xi$. Misalignments of up to 10 mm were considered and found to have a negligible impact. A misalignment of 10 mm is conservative compared with the survey precision and any known misalignments within the ATLAS experiment.

**Fractional diffractive event contribution.** The fractional contribution of diffractive events, $f_{\text{D}}$, is constrained by the ratio of single-sided to inclusive events, $R_{\text{in}}$. The MC generators predict that less than 1% of the ND process pass the single-sided event selection, whereas 27–41% of the SD and DD processes pass the single-sided selection. For all models, the inclusive sample is dominated by ND events; therefore, the ratio of single-sided to inclusive events is sensitive to the relative fraction of diffractive events.

The measured $R_{\text{in}}$ in the data is $R_{\text{in}} = [10.02 \pm 0.03 \text{(stat.)} ^{+0.1}_{-0.1} \text{(syst.)} \%]$, where the systematic error includes the uncertainties on the backgrounds, the MBTS response and the material.

Figure 1 compares the observed value of $R_{\text{in}}$ to the predictions of several models as a function of $f_{\text{D}}$. The intersection of the $R_{\text{in}}$ value measured in data with the prediction is used as the central value of $f_{\text{D}}$ for each model. The systematic uncertainty on $f_{\text{D}}$ is determined by the maximum and minimum values consistent with the 1σ uncertainty on the data when varying the double- to single-dissociation event ratio between 0 and 1. The resulting value using the default DL model is $f_{\text{D}} = 26.9^{+2.5}_{-1.9}$%.

**Uncertainty on acceptance.** The acceptance calculation relies on the MC generators to provide an adequate description of the particle multiplicity in the acceptance region. The validity of the MC description is assessed by examining the hit multiplicity in the MBTS detector in the inclusive and single-sided event samples as shown in Figure 2. Whereas none of the generators gives a perfect.
description, the data lie between the models at low multiplicity that is most important for the measurement.

The inclusive sample, which is dominated by non-diffractive events, is reasonably well described by the MC. In addition, inclusive charged particle properties have been studied extensively in\textsuperscript{37,38} that show that the Monte Carlo generators describe the data well. Differences in the acceptance for non-diffractive events were studied with several variations of the Pythia6 tuning parameters and were shown to be negligible.

The single-sided sample is dominated by diffractive events. The default DL model describes it well, giving confidence in the diffractive modelling. We use the difference in the MC correction factor determined with Pythia8 and Pythia6 as the uncertainty due to the fragmentation model, leading to a 0.4\% uncertainty on the cross-section. The maximum difference between the default DL model and all other models is taken as the uncertainty due to the underlying $\xi$ distribution. Variations of $\alpha'$ have a negligible effect on the acceptance. Among all the models considered, the Pyjet model gives the largest difference in the correction factor, leading to a 0.4\% uncertainty on the cross-section.

Inelastic cross-section. The final result for the measured inelastic cross-section is calculated using the default DL model of $\varepsilon=0.085$ and $\alpha'=0.25$, which yields $f_d=26.9\%$, $\epsilon_s=98.77\%$, and $\mathcal{F}_d=5.9\times10^{-6}$. Together with $\varepsilon_{\text{inv}}=99.98\%$, $N=1,220,743$, $N_{\text{MBTS}}=1,574$, and $\sqrt{s} = 20.25$ mb$^{-1}$ this results in $\sigma_{\text{inel}}(\xi > 5 \times 10^{-6}) = 60.3\pm0.05\text{ (stat.)}\pm0.5\text{ (syst.)}\pm2.1\text{ (lumi.)}$\ mb.

The systematic uncertainty includes all contributions discussed above and listed in Table 1. The dominant uncertainty arises from the luminosity calibration and is quoted separately.

Discussion

The measurement is compared with the predictions in Figure 3 and Table 2. The predictions by the Schuler–Sjöstrand model (66.4 mb) and the Pyjet model (74.2 mb) are both higher than the data. The prediction of 51.8–56.2 mb by Ryskin et al.\textsuperscript{17} and personal communication, is slightly lower than the data.

To compare with previous measurements and analytic models, the fractional contribution to the inelastic cross-section of events passing the $\xi>5\times10^{-6}$ cut is determined from the models and used to extrapolate the measurement to the full inelastic cross-section. This fraction is 87.3\% for the default model of DL with $\varepsilon=0.085$ and $\alpha'=0.25$. The other models considered give fractions ranging from 96\% (Pyjet) to 86\% (DL with $\varepsilon=0.10$). Recent calculations also yield values between 79 and 84\% (ref. 17). Thus

![Figure 1 | Dependence of the fraction of single-sided events ($R_s$) on the relative diffractive contribution ($f_d$). The ratio of the single-sided to inclusive event sample $R_s$ as a function of the fractional contribution of diffractive events, $f_d$, to the inelastic cross-section. The data value for $R_s$ is shown as the horizontal line with its systematic uncertainties (grey band). Also shown are predictions of several models as a function of an assumed value of $f_d$. For all three DL predictions, the $\alpha'$ value is 0.25 GeV$^{-2}$. The default $f_d$ values are indicated by the markers; they are 32.2\% for all models except Pyjet that uses 20.2\%.](image1)

![Figure 2 | MBTS multiplicity distributions. The MBTS multiplicity distribution in the data (filled circles) compared with MC expectations for the inclusive (a) and single-sided (b) samples for several MC models (histograms), using the fitted $f_d$ values. The band around the data indicates the systematic uncertainty due to the MBTS detector response and the amount of material in front of the MBTS detector. For all three DL predictions, the $\alpha'$ value is 0.25 GeV$^{-2}$.](image2)

Sources of systematic uncertainty and their effect on the cross-section measurement.
87.3% is taken as the default value for this fraction and an uncertainty of 10% is taken because of the extrapolation uncertainty on the $\xi$-dependence. The resulting inelastic cross-section value is $\sigma_{\text{inel}} = 69.1 \pm 2.4(\text{exp.}) \pm 6.9(\text{extr.})$ mb, where the experimental uncertainty includes the statistical and systematical errors, and the extrapolation uncertainty results from the uncertainty on the $\xi$-dependence of the cross-section.

This result is shown in Figure 3 and compared with several theoretical predictions and a variety of data at lower $\sqrt{s}$. The measurement within the kinematic range $\xi > 5 \times 10^{-6}$ is significantly lower than the predictions of Schuler and Sjöstrand and Phojet. The extrapolated value agrees within the large extrapolation uncertainty with the predictions from Pythia, which uses a power law dependence on $\xi$. It also agrees with Block and Halzen (which has a logarithmic $\sqrt{s}$ dependence), and with other recent theoretical predictions that vary between 60 and 72 mb (refs 87, 15). All measurements in this letter are made with the ATLAS detector, which is described in detail elsewhere (ref. 30).

The measurement and a variety of theoretical predictions are also summarized in Table 2.

In conclusion, a first measurement of the inelastic cross-section has been presented for $\sqrt{s} = 7$ TeV with a precision of 3.5%. The measurement is limited to the kinematic range corresponding to the detector acceptance: $\xi > 5 \times 10^{-6}$. Phenomenological predictions for both a power law dependence and a logarithmic rise of the cross-section with energy are consistent with the measurement.

Methods

The ATLAS detector. All measurements in this letter are made with the ATLAS detector, which is described in detail elsewhere (ref. 30). Here the detector coordinate system and sub-detectors relevant to this measurement are described.

ATLAS uses a right-handed coordinate system with its origin at the nominal interaction point in the centre of the detector and the $z$-axis aligned along the LHC beam pipe. The $x$-axis points from the interaction point to the centre of the LHC ring, and the $y$-axis points upwards. Cylindrical coordinates $(\varphi, \eta)$ are used in the transverse plane, $\varphi$ being the azimuthal angle around the beam pipe. The pseudorapidity is defined in terms of the polar angle $\theta$ as $\eta = -\ln \tan(\theta/2)$.

Physics Department, National Technical University of Athens, Zografou, Greece.
Institute of Physics, Azerbaijan Academy of Sciences, Baku, Azerbaijan.
Institut de Física d’Altes Energies and Universitat Autònoma de Barcelona and ICREA, Barcelona, Spain.
Institute of Physics, University of Belgrade, Belgrade, Serbia.
Department for Physics and Technology, University of Bergen, Bergen, Norway.
Physics Division, Lawrence Berkeley National Laboratory and University of California, Berkeley, California, USA.
Department of Physics, Humboldt University, Berlin, Germany.
Albert Einstein Center for Fundamental Physics and Laboratory for High Energy Physics, University of Bern, Bern, Switzerland.
School of Physics and Astronomy, University of Birmingham, Birmingham, UK.
Department of Physics, Bogazici University, Istanbul, Turkey; (b) Division of Physics, Dogus University, Istanbul, Turkey; (c) Department of Physics Engineering, Gaziantep University, Gaziantep, Turkey; (d) Department of Physics, Istanbul Technical University, Istanbul, Turkey.
INFN Sezione di Bologna, Bologna, Italy; (b) Dipartimento di Fisica, Università di Bologna, Bologna, Italy.
Physikalisches Institut, University of Bonn, Bonn, Germany.
Department of Physics, Boston University, Boston, Massachusetts, USA.
Department of Physics, Brandeis University, Waltham, Massachusetts, USA.
Universidade Federal do Rio de Janeiro COPPE/EE/IF, Rio de Janeiro, Brazil; (b) Instituto de Física, Universidade de Sao Paulo, Sao Paulo, Brazil.
Physics Department, Brookhaven National Laboratory, Upton, New York, USA.
National Institute of Physics and Nuclear Engineering, Bucharest, Romania; (b) University Politehnica Bucharest, Bucharest, Romania; (c) West University in Timisoara, Timisoara, Romania.
Departamento de Física, Universidad de Buenos Aires, Buenos Aires, Argentina.
Cavendish Laboratory, University of Cambridge, Cambridge, UK.
Department of Physics, Carleton University, Ottawa, Ontario, Canada.
CERN, Geneva, Switzerland.
Enrico Fermi Institute, University of Chicago, Chicago, Illinois, USA.
Departamento de Física, Pontificia Universidad Católica de Chile, Santiago, Chile; (b) Departamento de Física, Universidad Técnica Federico Santa María, Valparaíso, Chile.
Institute of High Energy Physics, Chinese Academy of Sciences, Beijing, China; (b) Department of Modern Physics, University of Science and Technology of China, Anhui, China; (c) Department of Physics, Nanjing University, Jiangsu, China; (d) High Energy Physics Group, Shandong University, Shandong, China.
Laboratoire de Physique Corpusculaire, Clermont Université and Université Blaise Pascal and CNRS/IN2P3, Aubiere Cedex, France.
Nevis Laboratory, Columbia University, Irvington, New York, USA.
Niels Bohr Institute, University of Copenhagen, Copenhagen, Denmark.
INFN Gruppo Collegato di Cosenza, Arcavacata di Rende, Italy; (b) Dipartimento di Fisica, Università della Calabria, Arcavacata di Rende, Italy.
Faculty of Physics and Applied Computer Science, AGH-University of Science and Technology, Krakow, Poland.
The Henryk Niewodniczanski Institute of Nuclear Physics, Polish Academy of Sciences, Krakow, Poland.
Physics Department, Southern Methodist University, Dallas, Texas, USA.
Physics Department, University of Texas at Dallas, Richardson, Texas, USA.
DESY, Hamburg and Zeuthen, Germany.
Institut für Experimentelle Physik IV, Technische Universität Dortmund, Dortmund, Germany.
Institut für Kern- und Teilchenphysik, Technical University Dresden, Dresden, Germany.
Department of Physics, Duke University, Durham, North Carolina, USA.
SUPA—School of Physics and Astronomy, University of Edinburgh, Edinburgh, UK.
Fachhochschule Wiener Neustadt, Wiener Neustadt, Austria.
INFN Laboratori Nazionali di Frascati, Frascati, Italy.
Fakultät für Mathematik und Physik, Albert-Ludwigs-Universität, Freiburg i.Br., Germany.
Section de Physique, Université de Genève, Geneva, Switzerland.
INFN Sezione di Genova, Genova, Italy; (b) Dipartimento di Fisica, Università di Genova, Genova, Italy.
Institute of Physics and HEP Institute, Georgian Academy of Sciences and Tbilisi State University, Tbilisi, Georgia.
II Physikalisches Institut, Justus-Liebig-Universität Giessen, Giessen, Germany.
SUPA—School of Physics and Astronomy, University of Glasgow, Glasgow, UK.
II Physikalisches Institut, Georg-August-Universität, Göttingen, Germany.
Laboratoire de Physique Subatomique et de Cosmologie, Université Joseph Fourier and CNRS/IN2P3 and Institut National Polytechnique de Grenoble, Grenoble, France.
Department of Physics, Hampton University, Hampton, Virginia, USA.
Laboratory for Particle Physics and Cosmology, Harvard University, Cambridge, Massachusetts, USA.
Krechhoff-Institut für Physik, Ruprecht-Karls-Universität Heidelberg, Heidelberg, Germany; (b) Physikalisches Institut, Ruprecht-Karls-Universität Heidelberg, Heidelberg, Germany; (c) ZITI Institut für technische Informatik, Ruprecht-Karls-Universität Heidelberg, Mannheim, Germany.
Laboratorio de Instrumentacao e Fisica Experimental de Particulas - LIP, Lisboa, Portugal; Departamento de Fisica Teorica y del Cosmos and CAFPE, Universidad de Granada, Granada, Spain.

Institute of Physics, Academy of Sciences of the Czech Republic, Praha, Czech Republic.

Faculty of Mathematics and Physics, Charles University in Prague, Praha, Czech Republic.

Czech Technical University in Prague, Praha, Czech Republic.

State Research Center Institute for High Energy Physics, Protvino, Russia.

Particle Physics Department, Rutherford Appleton Laboratory, Didcot, UK.

Physics Department, University of Regina, Regina, Saskatchewan, Canada.

Ritsumeikan University, Kusatsu, Shiga, Japan.

INFN Sezione di Roma I, Roma, Italy; Dipartimento di Fisica, Universitá La Sapienza, Roma, Italy.

INFN Sezione di Roma Tor Vergata, Roma, Italy; Dipartimento di Fisica, Universitá di Roma Tor Vergata, Roma, Italy.

INFN Sezione di Roma Tre, Roma, Italy; Dipartimento di Fisica, Universitá Roma Tre, Roma, Italy.

Faculté des Sciences Ain Chock, Réseau Universitaire de Physique des Hautes Energies - Université Hassan II, Casablanca, Morocco; Centre National de l’Énergie des Sciences Techniques Nucleaires, Rabat, Morocco; Université Cadi Ayyad, Faculté des sciences Semlia Département de Physique, B.P. 2390 Marrakech 40000, Morocco; Faculté des Sciences, Université Mohamed Premier and LPTPM, Oujda, Morocco; Faculté des Sciences, Université Mohammed V, Rabat, Morocco.

DSM/IRFU (Institut de Recherches sur les Lois Fondamentales de l’Univers), CEA Saclay (Commissariat à l’Energie Atomique), Gif-sur-Yvette, France.

Santa Cruz Institute for Particle Physics, University of California Santa Cruz, Santa Cruz, California, USA.

Department of Physics, University of Washington, Seattle, Washington, USA.

Department of Physics and Astronomy, University of Sheffield, Sheffield, UK.

Department of Physics, Shinshu University, Nagano, Japan.

Fachbereich Physik, Universität Siegen, Siegen, Germany.

Department of Physics, Simon Fraser University, Burnaby, British Columbia, Canada.

SLAC National Accelerator Laboratory, Stanford, California, USA.

Faculty of Mathematics, Physics & Informatics, Comenius University, Bratislava, Slovak Republic; Department of Subnuclear Physics, Institute of Experimental Physics of the Slovak Academy of Sciences, Kosice, Slovak Republic.

Department of Physics, University of Johannesburg, Johannesburg, South Africa; School of Physics, University of the Witwatersrand, Johannesburg, South Africa.

Department of Physics, Stockholm University, Stockholm, Sweden; The Oskar Klein Centre, Stockholm, Sweden.

Physics Department, Royal Institute of Technology, Stockholm, Sweden.

Department of Physics and Astronomy, Stony Brook University, Stony Brook, New York, USA.

Department of Physics and Astronomy, University of Sussex, Brighton, UK.

School of Physics, University of Sydney, Sydney, Australia.

Institute of Physics, Academia Sinica, Taipei, Taiwan.

Department of Physics, Technion: Israel Inst. of Technology, Haifa, Israel.

Raymond and Beverly Sackler School of Physics and Astronomy, Tel Aviv University, Tel Aviv, Israel.

Department of Physics, Aristotle University of Thessaloniki, Thessaloniki, Greece.

International Center for Elementary Particle Physics and Department of Physics, The University of Tokyo, Tokyo, Japan.

Graduate School of Science and Technology, Tokyo Metropolitan University, Tokyo, Japan.

Department of Physics, Tokyo Institute of Technology, Tokyo, Japan.

Department of Physics, University of Toronto, Toronto, Ontario, Canada.

TRIUMF, Vancouver British Columbia, Canada; Department of Physics and Astronomy, York University, Toronto, Ontario, Canada.

Institute of Pure and Applied Sciences, University of Tsukuba, Ibaraki, Japan.

Science and Technology Center, Tufts University, Medford, Massachusetts, USA.

Centro de Investigaciones, Universidad Antonio Narino, Bogota, Colombia.

Department of Physics and Astronomy, University of California Irvine, Irvine, California, USA.

INFN Gruppo Collegato di Udine, Udine, Italy; ICTP, Trieste; Dipartimento di Fisica, Università di Udine, Udine, Italy.

Department of Physics, University of Illinois, Urbana, Illinois, USA.

Department of Physics and Astronomy, University of Uppsala, Uppsala, Sweden.

Instituto de Física Corpuscular (IFIC) and Departamento de Física Atómica, Molecular y Nuclear and Departamento de Ingeniería Electrónica and Instituto de Microelectrónica de Barcelona (IMB-CNM), University of Valencia and CSIC, Valencia, Spain.

Department of Physics, University of British Columbia, Vancouver, British Columbia, Canada.

Department of Physics and Astronomy, University of Victoria, Victoria, British Columbia, Canada.

Waseda University, Tokyo, Japan.

Department of Particle Physics, The Weizmann Institute of Science, Rehovot, Israel.

Department of Physics, University of Wisconsin, Madison, Wisconsin, USA.

Fakultät für Physik und Astronomie, Julius-Maximilians-Universität, Würzburg, Germany.

Fachbereich C Physik, Bergische Universität Wuppertal, Wuppertal, Germany.

Department of Physics, Yale University, New Haven, Connecticut, USA.

Yerevan Physics Institute, Yerevan, Armenia.

Domaine scientifique de la Doua, Centre de Calcu CNRS-IN2P3, Villeurbanne Cedex, France.

Also at Laboratorio de Instrumentacao e Fisica Experimental de Particulas - LIP, Lisboa, Portugal.

Also at Facultade de Ciencias and CFNUL, Universidade de Lisboa, Lisboa, Portugal.

Also at CPPM, Aix-Marseille Université and CNRS-IN2P3, Marseille, France.

Also at TRIUMF, Vancouver, British Columbia, Canada.

Also at Department of Physics, California State University, Fresno, California, USA.
†Also at Faculty of Physics and Applied Computer Science, AGH-University of Science and Technology, Krakow, Poland.
*Also at Department of Physics, University of Coimbra, Coimbra, Portugal.
+Also at Università di Napoli Parthenope, Napoli, Italy.
#Also at Institute of Particle Physics (IPP), Canada.
$Also at Department of Physics, Middle East Technical University, Ankara, Turkey.
%Also at Louisiana Tech University, Ruston, Louisiana, USA.
&Also at Group of Particle Physics, University of Montreal, Montreal, Québec, Canada.
**Also at Institute of Physics, Azerbaijan Academy of Sciences, Baku, Azerbaijan.
*)&Also at Institut für Experimentalphysik, Universität Hamburg, Hamburg, Germany.
+)&Also at Manhattan College, New York, New York, USA.
&&Also at School of Physics and Engineering, Sun Yat-sen University, Guanzhou, China.
&&*Also at Academia Sinica Grid Computing, Institute of Physics, Academia Sinica, Taipei, Taiwan.
&&#Also at High Energy Physics Group, Shandong University, Shandong, China.
&&$Also at California Institute of Technology, Pasadena, California, USA.
&&%Also at Particle Physics Department, Rutherford Appleton Laboratory, Didcot, UK.
&&&Also at Section de Physique, Université de Genève, Geneva, Switzerland.
&&&Also at Departamento de Física, Universidade de Minho, Braga, Portugal.
&&&&Also at Department of Physics and Astronomy, University of South Carolina, Columbia, South Carolina, USA.
&&&&Also at KFKI Research Institute for Particle and Nuclear Physics, Budapest, Hungary.
&&&&Also at Institute of Physics, Jagiellonian University, Krakow, Poland.
&&&&Also at Department of Physics, Oxford University, Oxford, UK.
&&&&*Also at DSM/IRFU (Institut de Recherches sur les Lois Fondamentales de l’Univers), CEA Saclay (Commissariat a l’Energie Atomique), Gif-sur-Yvette, France.
&&&&+Also at Laboratoire de Physique Nucléaire et de Hautes Energies, UPMC and Université Paris-Diderot and CNRS/IN2P3, Paris, France.
&&&&*Also at Department of Physics, Nanjing University, Jiangsu, China.
&&&&†Deceased.
