Keywords: Fullerenes, Diels–Alder Cycloaddition, Organic Solar Cells, Bulk Heterojunction Photovoltaics

We have developed new tetraalkycyclobutadiene–C_{60} adducts, via Diels–Alder cycloaddition of C_{60} with in situ generated cyclobutadienes. The cofacial π-orbital interactions between the fullerene orbitals and the cyclobutene are shown to decrease the electron affinity and thereby increase the LUMO energy level of C_{60} significantly (ca. 100 meV and 300 meV for mono- and bisadducts, respectively). These variations in LUMO levels of fullerene can be used to generate higher open-circuit voltages (V\textsubscript{OC}) in bulk heterojunction polymer solar cells. The tetramethylcyclobutadiene–C_{60} monoadduct displays an open-circuit voltage (0.61 V) and a power conversion efficiency (2.49%) comparable to the widely used P3HT/PCBM composite (0.58V and 2.57% respectively). The role of the cofacial π-orbital interactions between C_{60} and the attached cyclobutene group was probed chemically by epoxidation of the cyclobutene moiety
and theoretically through density functional theory (DFT) calculations. The electrochemical, photophysical, and thermal properties of the newly synthesized fullerene derivatives support the proposed effect of functionalization on electron affinities and photovoltaic performance.

1. Introduction

Bulk heterojunction (BHJ) polymer solar cells (PSCs), composed of conjugated polymer donors and small or macromolecule acceptors, are leading compositions in the quest for practical organic photovoltaic cells. [1,2] The bicontinuous nature of the phases in BHJ creates a large surface to volume ratio for efficient exciton dissociation, and facile and low-cost fabrication methods are compatible with large scale production.[3,4] Despite extensive efforts to improve the properties of the constituent materials and morphologies of BHJ systems, competing with the power conversion efficiency (PCE) of silicon-based solar cells remains a challenge. [5] In pursuit of ideal BHJ electronic structures, researchers have developed low band gap p-type polymers that strongly absorb high fractions of the solar spectrum and assemble into desirable film morphologies.[6,7] Efforts to improve n-type acceptor components have included BHJs with small molecules such as 9,9’-bifluorenyldienes, perylenediimides, and vinazenes. [8-10]

Nevertheless, fullerenes are presently the most widely used and highest performing materials in part due to their high electron affinities and low reorganization energies for electron transfer. [11] Tailoring the electronic structure of fullerene is therefore of interest, and reactions with organometallic reagents, radicals, and transition-metal complexation have been investigated to create new fullerenes for BHJs.[12-14] The reactivity of fullerene resembles that of an electron-deficient polyolefin, and as such, a dominant functionalization strategy has been to use cycloaddition reactions.[15,16] Noteworthy examples include the synthesis of PCBM ([6,6]-
phenyl-C_{61}-butyric acid methyl ester) via 1,3-dipolar cycloaddition and indene–C_{60} adducts from Diels–Alder reactions.\textsuperscript{[17–19]}

Less-than-optimal band offsets at the BHJs can lead to energy loss and low open-circuit voltages in solar cells. In order to increase power conversion efficiencies, there have been efforts to increase the HOMO_{D}–LUMO_{A} (A: acceptor, D: donor) gap which is often considered to be proportional to the open-circuit voltage.\textsuperscript{[20]} Many polymer donors with alternating electron-rich and electron-poor units have been designed for optimized absorption of the solar spectrum. Decreasing the HOMO energy of the donor polymers can be accomplished by simple modifications of the electron-rich repeating units, but this typically leads to an expanded band gap that reduces the solar absorption efficiency, thereby giving a smaller short-circuit current density (J_{SC}).\textsuperscript{[21–23]} As a result, an alternative, and perhaps more predictive, method is to increase the LUMO energy level of the fullerenes to create increased V_{OC}s. Most C_{60} functionalization methods, including cycloaddition reactions, break the full conjugation of the C_{60} \pi-system and generally decrease the electron affinity and raise the LUMO level.\textsuperscript{[24]} The extent of this change varies depending on the nature of the functional groups attached to the C_{60} core. The decreased relative electron affinity of C_{60} is measured by the change of the onset reduction potential or the calculated LUMO level.\textsuperscript{[25,26]} In this context, there has recently been interest in indene–C_{60} acceptors because these materials exhibit ca. 50–170 mV reduced electron affinities (higher LUMO) relative to PCBM.\textsuperscript{[27]} It would appear that the short distance between the C_{60} \pi-system and the \pi-orbitals of the addend aromatic ring of the indene affects the LUMO energy.

To expand upon the hypothesis that cofacial \pi-orbital interactions between C_{60} and an attached group can effectively raise the fullerene LUMO levels, we have targeted a new functionalization method that makes use of the well-known zwitterionic AlCl_{3}–cyclobutadiene adducts. The
release of the cyclobutadienes by treatment of alkyne–AlCl₃ adducts with weak Lewis bases has been found to result in Diels–Alder reactions with alkynes (Scheme 1) to give Dewar benzene products that have fairly small angles (114.6–114.9°) between two cyclobutene rings. As a result, we rationalized that Diels–Alder adducts of similarly generated cyclobutadiene adducts with fullerenes could give rise to strong cofacial π-orbital interactions.

In this study we report the syntheses of mono- and multiadducts of tetramethylcyclobutadienes (Scheme 2) and tetrabutylcyclobutadienes to fullerenes (Figure 1). The electrochemical, photophysical, and thermal properties of these new fullerenes have been studied, and their use in photovoltaic devices with poly(3-hexylthiophene) (P3HT) has been evaluated in comparison with PCBM. Tetramethylcyclobutadiene–C₆₀ mono-, bis-, and trisadducts (TMCB-Mono, TMCB-Bis, and TMCB-Tris) all exhibited higher open-circuit voltages than that of PCBM, and TMCB-Mono showed comparable power conversion efficiency (2.49%) to PCBM (2.57%) devices under the identical conditions. Lastly, the π-orbital interactions between cyclobutene and the C₆₀ cage were probed by removing the appended double bond by epoxidation. The increased electron affinity of the cyclobutane–epoxide–C₆₀ was measured by cyclic voltammetry and calculated using density functional theory. All of our results are consistent with the hypothesis that π–π orbital interactions are an effective means to adjust the fullerene LUMO levels.

2. Results and Discussion
2.1. Syntheses of Tetraalkylcyclobutadiene–C₆₀ Adducts
It is well-known that aluminum chloride reacts with internal alkynes to generate cyclobutadiene intermediates with a σ-bonded aluminum moiety (Scheme 1). The intermediate cyclobutadiene, which is liberated by addition of dimethylsulfoxide, is very reactive in [4+2] cycloaddition reactions either as a diene (Scheme 1) or as a reactive alkene. C₆₀ is a potent
dienophile\textsuperscript{[31]} and new n-type C\textsubscript{60} derivatives are created via Diels–Alder reactions with the \textit{in situ} generated tetraalklylcyclobutadienes.

The reactions were run under moisture-free conditions wherein the reaction of 2-butyne and aluminum chloride was first combined with C\textsubscript{60} and subsequent treatment with DMSO produced tetramethylcyclobutadiene–C\textsubscript{60} mono-, bis-, and trisadducts (Scheme 2). By varying the molar ratio of the alkyne, aluminum chloride, and C\textsubscript{60}, we were able to selectively increase the yield of each product in the mixture. In many cases, the syntheses of functionalized fullerenes involve tens of equivalents of the non-fullerene reagents to ensure a high-yielding functionalization.\textsuperscript{[27,32]}

In contrast, four equivalents of 2-butyne relative to C\textsubscript{60} produce monoadduct and bisadduct in isolated respective yields of 32\% and 17\% after rigorous purification. Generation of four equivalents of cyclobutadiene (8 eq. of 2-butyne) increases the isolated yield of the pure trisadduct to 8\%. It is also the case that the syntheses of fullerene derivatives by Diels–Alder reactions often require long reaction times,\textsuperscript{[33]} and high temperatures such as refluxing \textit{o}-dichlorobenzene (b.p. 180.5\textdegree{}C).\textsuperscript{[32]} The cyclobutadiene addition was carried out at low temperatures (between 0\textdegree{}C and room temperature) with reaction times of less than 2 hours. After the reaction, the mixture of fullerene adducts was separated by HPLC using a 5PBB Cosmosil column with toluene elution. $^1$H and $^{13}$C nuclear magnetic resonance (NMR) spectroscopy as well as high-resolution mass spectrometry (HRMS) confirmed the attachment of the cyclobutene moiety. The similar procedure provided other tetraalklycyclobutadiene–C\textsubscript{60} adducts starting with symmetric internal alkynes such as 3-hexyne, 4-octyne, and 5-decyne (Scheme S1). The longer alkyl products provide for high solubility in organic solvents such as chloroform, dichloromethane, and toluene. Longer chains disfavor trisadduct formation, presumably due to the steric strain on the C\textsubscript{60} surface. For example, for the functionalization starting with 5-decyne,
we could not observe the trisadduct even when using 16 equivalents of this alkyne. Figure 1
details the representative five new functionalized fullerenes selected for further investigation and
the well-known PCBM.

2.2. Electrochemical Properties

C\textsubscript{60} has triply-degenerated low-lying LUMO energy levels and thereby can be reduced by up
to six electrons.\textsuperscript{[34]} A series of cyclic voltammograms in Figure 2 shows that three or four
reversible redox waves are retained in the functionalized fullerenes under anhydrous air-free
conditions, relative to the ferrocene/ferrocenium (Fc/Fc\textsuperscript{+}) internal standard peaks at ca. 200 mV
(±0.5 mV).

The monoadducts (TMCB-Mono and TBCB-Mono) exhibited four reversible redox peaks
(Figure 2a and 2b), which are all shifted to negative potentials by ca. 100 mV as compared to
PCBM, and the bisadducts showed an additional ca. 200 mV shift relative to the monoadducts.
The measured half-wave potentials are listed in Table 1 together with the estimated LUMO
energy levels relative to the vacuum level. The cyclic voltammogram of the trisadduct contained
three major sets of the redox peaks, as well as another set of peaks, which we assume to be a
persistent tetrakisadduct impurity (Figure 2a). Despite the less defined features, it is clear that the
three main redox waves are further shifted by about 200 mV as compared to the bisadduct. The
reversible sets of redox curves shown in Figure 2(a) and 2(b) confirm that the functionalization
preserves the key electronic accepting characteristics of C\textsubscript{60}. The pronounced negative shifts of
redox curves and the corresponding increase of LUMO energy levels relative to PCBM (90 meV
for TMCB-Mono, 260 meV for TMCB-Bis, and 450 meV for TMCB-Tris) are considerably
greater than the indene–C\textsubscript{60} mono- and bisadducts (50 meV and 170 meV, respectively).\textsuperscript{[27]} This
behavior is consistent with our designs that make use of the small angles between fused four-membered rings, which increases the $\pi$-orbital interaction between the pendant cyclobutene moiety and C$_{60}$ centered states. It is not straightforward to explain the difference in LUMO shifts of indene–C$_{60}$ and cyclobutadiene–C$_{60}$. The proximity of the addend $\pi$-orbitals to C$_{60}$ surface, or the angle between two rings, of either compound has not been determined and crystal structures have not been obtained to date. The different extent of LUMO shifts could be also influenced by other factors, given two dissimilar addend structures.

The cyclic voltammograms of TMCB-adducts and TBCB-adducts are similar in terms of the shape and the positions of potentials, but the TBCB-adducts exhibit slightly more negative redox potentials. Considering the higher LUMOs of the TBCB-series we expect a slightly higher $V_{oc}$ in photovoltaic devices relative to those obtained for TMCB-adducts.

### 2.3. Photophysical Properties

The visible and near-infrared spectral absorptions of BHJ devices are a major determinant of solar cell efficiencies. $J_{sc}$ is dependent on the number of charge carriers generated and their mobility. Considerable efforts have focused on creating donor polymers with band gaps that match the solar spectrum. Although $J_{sc}$ is generally dominated by the photon collection of the donor polymer, stronger visible light absorption of the acceptors can also contribute to light harvesting. Specifically, the weak optical absorptions of PCBM are considered a limitation and have led to interest in more costly C$_{70}$ acceptor materials. In Figure 3, we show comparative absorption spectra (400 nm–800 nm) of our new fullerene derivatives relative to PCBM. The cyclobutadiene functionalized fullerenes exhibited the similar or higher absorptivity relative to PCBM. A more intense absorption was observed for the higher adducts, which is consistent with
desymmetrization of fullerenes. The weak spikes around 430 nm for TMCB- and TBCB-Mono are characteristic for 1,2-addition products, which confirms the structures depicted in Scheme 2. A hypothetical 1,4-adduct, which would form if C\textsubscript{60} acted as a diene and cyclobutadiene as a dienophile, would exhibit a broad absorption band around 450 nm, instead.\textsuperscript{[36-39]} The absorption peaks around 430 nm are slightly red-shifted from those of PCBM. Additionally, the bis- and trisadducts showed broader absorptions as a result of the fact that they are a mixture of regioisomers. Based upon their absorption properties these new fullerene derivatives appear to offer advantages over PCBM in terms of the higher absorptivity and the red-shifted absorption edge around 700 nm. The absorption edge wavelengths, \( \lambda_{\text{onset}} \), vary from 697 nm to 751 nm, and longer wavelengths were observed for bisadducts than monoadducts and PCBM (Table 1). The trisadduct is a 56-\( \pi \)-electron fullerene and deviates from the trend with a small value of \( \lambda_{\text{onset}} \). The band gaps and the HOMO energy levels of the fullerenes were calculated from \( \lambda_{\text{onset}} \) and the first reduction wave, and are summarized in Figure 4 and Table 1.

2.4. Thermal Properties

The thermal stability of the molecules was determined by thermogravimetric analysis (TGA), which revealed weight loss of less than 5% at 200\(^\circ\)C under N\(_2\) atmosphere (Figure S2). All functionalized fullerenes are less stable than pristine C\textsubscript{60}, which has outstanding thermal stability up to 500–600\(^\circ\)C.\textsuperscript{[40]} C\textsubscript{60} derivatives often display a change in morphology or decomposition at around 150\(^\circ\)C, and the typical annealing temperatures used in polymer solar cell fabrications affect their performance. To further investigate the thermal properties of the fullerene adducts and the effects of annealing, we conducted differential scanning calorimetry (DSC) experiments over the range from 25\(^\circ\)C to 200\(^\circ\)C (Figure S3). In the first cycle, a strong and broad exothermic
heat flow was observed for TMCB-Bis and Tris from 90°C to 150°C and 80°C to 190°C, respectively (Figure S3 (a)).

In contrast, the TMCB-Mono displays a small endothermic peak which starts to appear at ca. 110°C, which is likely due to loss of residual toluene (b.p. 111°C). The second DSC cycles were featureless for all of the compounds (Figure S3 (b)). The mono- and bisadducts of tetrabutylcyclobutadiene exhibited relatively featureless heat flow to their tetramethyl counterparts (Figure S3 (c, d)).

BHJs formed with P3HT after annealing at 150°C for 20 min were studied by atomic force microscopy (AFM) (Figure 5). The larger grain sizes (root-mean-square roughness) and more pronounced phase separation were observed in the films with higher adducts. The P3HT/TMCB-Mono morphology most closely resembled the roughness of the P3HT/PCBM blend. We were interested in determining if any of the features observed for the higher adducts in the DSC and AFM reflected thermal decomposition or only morphology changes. Indeed our new fullerene derivatives could be susceptible to retro-cycloaddition reactions as other fullerene cycloadducts. \[41,42\] In order to investigate this, we measured the \(^1\text{H}\) NMR spectra of the fullerene derivatives after three DSC cycles (25°C–200°C, 10°C/min) (Figure S4 (a, b)). The TMCB-Bis gained the peaks assignable to TMCB-Mono, and TMCB-Tris gained the peaks indicating the generation of TMCB-Mono and TMCB-Bis. As a result, it is possible that larger phase separation of the BHJ layers with the multiadducts is related to conversion of the fullerene multiadducts into less-functionalized adducts upon annealing. The \(^1\text{H}\) NMR spectra of the TMCB-Mono, TBCB-Mono, and TBCB-Bis after being subjected to three DSC cycles did not display any detectable changes thereby reconfirming their superior thermal stability as compared to the TMCB multiadducts. To determine if crystallization might also be responsible for the exothermic DSC transitions of the
TMCB multiadducts at high temperatures, we conducted X-ray diffraction experiments (Figure S5 (a, b)). TMCB and TBCB monoadducts are a single regioisomer, presumably fused to C_{60} in [6,6]-closed fashion as usual Diels–Alder cycloaddition products of C_{60}, and exhibit microcrystallinity. The butyl groups on cyclobutadiene–C_{60}, as expected, produce a larger lattice spacing (11.2 Å) than methyl groups (10.1 Å). For multiadducts, the mixture of isomers reduced the crystallinity of the sample, and TMCB-Bis remained in an amorphous state even after three DSC cycles. As a result, the observed DSC exothermic transitions for the multiadducts are most likely the result of retro-cycloaddition reactions. In an attempt to produce a more stable analog, the reaction of C_{60} and naphthocyclobutadiene was conducted. However, the reaction did not proceed, presumably as a result of the fact that the tetraalkylcyclobutadiene behaves as the diene in the Diels Alder reaction and naphthocyclobutadiene would only be expected to behave as the dienophile.

2.5. Organic Photovoltaic Performances

Figure 6 details current density versus voltage (J–V) characteristics under illumination of select P3HT/fullerene BHJ solar cells. Specifically TMCB-Mono, Bis, and Tris are compared to the well-known P3HT/PCBM system. As predicted based on the LUMO energy levels, TMCB-Mono gives a higher open-circuit voltage than PCBM. The P3HT/TMCB-Mono system also displays a short-circuit current density, fill factor, and PCE (\(\eta\)) comparable to the P3HT/PCBM device. The J–V curve of TMCB-Bis displays a higher \(V_{OC}\), consistent with its higher LUMO level, but a much lower \(J_{SC}\) and decreased fill factor lead to poor efficiency. We expect that the thermal instabilities of the higher fullerene cyclobutadiene adducts contributes to lower efficiencies. The performance of the P3HT/TMCB-Tris cell displays even lower \(J_{SC}\). Field-effect
mobilities of electrons are also decreased for the higher adducts in comparison to TMCB-Mono and the standard PCBM. Values of $2.53 \times 10^{-3}$ cm$^2$/V·s for PCBM, $1.08 \times 10^{-3}$ cm$^2$/V·s for TMCB-Mono, $1.07 \times 10^{-5}$ cm$^2$/V·s for TMCB-Bis, and $1.34 \times 10^{-6}$ cm$^2$/V·s for TMCB-Tris were obtained. An interesting feature is that the open-circuit voltage of TMCB-Tris is smaller than that of TMCB-Bis. This discrepancy might result from the excessive decomposition of Tris upon annealing. In general, the open-circuit voltages of the BHJ polymer-fullerene films are influenced by intermolecular interactions in the solid state. Thus, they can exhibit quantitatively non-linear correlation with HOMO$_{H}$–LUMO$_{A}$ gaps, predicted by the solution-state measurements. Additionally, we note that the $V_{OC}$ in organic BHJ solar cells is recombination limited.\(^{[46]}\) Since we observe non-ideal BHJ morphologies with some of our fullerene adducts, which increases the rate of bimolecular recombination across the donor-acceptor interface, we hypothesize that part of the observed discrepancy in $V_{OC}$ trends is also due to increased recombination. Correspondingly, the PCE (Table 2) of P3HT/TMCB-Mono (2.49%), comparable with that of P3HT/PCBM (2.57%), and the smaller values for P3HT/TMCB-Bis (1.35%) and P3HT/TMCB-Tris (0.65%) were consistent with the degree of phase separation and root-mean-square roughness discovered on AFM images.

In order to obtain the optimized performance of fullerene adducts with longer alkyl chains, we annealed the devices with TBCB-Mono and TBCB-Bis at 90° C (Figure S6). P3HT/TBCB-Mono blend produced higher $V_{OC}$ (0.64 V) and $J_{SC}$ (9.72 mA/cm$^2$) compared to P3HT/PCBM (Figure S6), but the increased resistance in the blend resulted in lower fill factor and comparable PCE (2.43%). The decreased $V_{OC}$ (0.61 V) and $J_{SC}$ (1.37 mA/cm$^2$) of P3HT/TBCB-Bis cell led to poor PCE (0.23%), thus reconfirming that less desirable performances are obtained from our multiadducts. In addition, the comparison of the J–V curves from different annealing conditions
(90 °C and 120° C) reflected the destructive effect of thermal annealing at high temperatures on the cells.

2.6. Elimination of π-Orbital Interaction

In order to chemically probe our hypothesis that large decrease in electron affinity in the cyclobutadiene-fullerenes is the result of strong interactions between the cyclobutene double bond and the C_{60} π-system, we devised a simple experiment to remove the double bond. Several reactions were attempted, but the most straightforward and the highest-yielding reaction was epoxidation with 3-chloroperbenzoic acid (mCPBA) (Scheme 3). The reaction proceeded with 96% yield, and the product (TMCB-EP) had significantly different polarity from the starting material, which facilitated purification. The identity of the product was supported by ^1H and ^13C NMR spectra as well as HRMS. Epoxidation of TBCB-Mono was unsuccessful presumably as a result of steric hindrance around the reaction site, and only starting material was recovered.

Cyclic voltammetry of TMCB-Ep (Figure 7) exhibited four reversible redox peaks like other monoadducts, but half-wave potentials were located approximately half way between those of pristine C_{60} and the TMCB-Mono compound. In Table 3, the half-wave potentials of TMCB-Ep were summarized. The difference between LUMO energy levels of C_{60} and TMCB-Ep is 60 meV, and the gap between those of TMCB-Ep and TMCB-Mono is 50 meV. From this observation, we conclude that orbital interactions between the cofacial cyclobutene and C_{60} π-systems contribute to the observed LUMO raising. The electron affinity of TMCB-Ep was still lower than that of C_{60} and this is presumably the result of the σ-π hyperconjugative interactions.

To further support this assertion, we conducted quantum-chemical density functional theory (DFT) calculations (B3LYP functional/6-31G (d,p) basis set) of TMCB-Mono and TMCB-Ep.
The geometry optimized structures (Figure S7 (a), (b)) had HOMO and LUMO energy levels of −5.57 eV and −3.04 eV for TMCB-Mono, and −5.69 eV and −3.16 eV for TMCB-Ep (Figure S8 (a), (b)). These results also indicated that epoxidation of the cyclobutene moiety decreased the LUMO level. The calculated distances between C$_{60}$ cage and the attached functional groups were 3.05 Å and 3.10 Å for TMCB-Mono and TMCB-Ep, sufficiently short to allow for cofacial $\pi$-orbital interactions.\textsuperscript{[47]} It is apparent in the LUMO representations (side and front views on Figure S8(a)) of TMCB-Mono that the wavefunction on the double bond of the cyclobutene moiety and that on the adjacent C$_{60}$ $\pi$-orbital possess the opposite signs. It is believed that the LUMO level of C$_{60}$ is raised effectively due to this close $\pi$-$\pi$ interaction between the two moieties. On the other hand, for TMCB-Ep (Figure S8(b)), the hyperconjugative interaction between the C–H $\sigma$-bonds of methyl groups and C$_{60}$ $\pi$-system is outstanding for most of the MOs rather than cofacial $\pi$ interaction. Therefore, we could theoretically support the concept of the structural design of cyclobutadiene–C$_{60}$ for efficient cofacial $\pi$ interaction and the experimental results.

3. Conclusions

Two families of tetraalkylcyclobutadiene–C$_{60}$ adducts were generated via Diels–Alder cycloaddition reactions between \textit{in situ} generated cyclobutadiene intermediates and C$_{60}$. The mono-, bis-, and trisadducts of C$_{60}$ with tetraalkylcyclobutadiene groups were formed, and their electrochemical, photophysical, and thermal properties were compared. The thermal annealing process in device fabrication was revealed to be destructive for the new fullerene bis- and trisadducts, leading to large phase separation and low PCEs. Epoxidation of cyclobutene confirmed that strong cofacial $\pi$-orbital interactions between C$_{60}$ $\pi$-system and the double bond
π-orbital contribute to raising the LUMO levels. Our results show that n-type materials for bulk heterojunction polymer solar cells can be chemically modified to fine-tune their electronic properties and thus the resulting open-circuit voltages in organic solar cells.

4. Experimental Section

Materials. C_{60} was purchased from SES Research, and aluminum chloride and alkynes were purchased from Sigma–Aldrich and used as received. Other materials including solvents and electrolyte salt were commercially available. Anhydrous solvents were obtained from a solvent purification system (Innovative Technologies).

Measurements. Reaction mixtures containing multiadducts of fullerenes were separated by 5PBB Cosmosil column (10 mm x 250 mm) from Nacalai Tesque, Inc. installed in Agilent Technologies ProsStar 210 High Pressure Liquid Chromatography (HPLC) system. \textsuperscript{1}H and \textsuperscript{13}C NMR spectra were taken on Varian Inova–500 spectrometers. Chemical shifts were reported in ppm and referenced to residual solvent peaks (CDCl\textsubscript{3}: 7.26 ppm for \textsuperscript{1}H, 77.20 ppm for \textsuperscript{13}C). Thermally assisted direct analysis in real time (TA–DART)[48] high-resolution mass spectrometry (HRMS) was measured on LCQ DECA (Thermo–Finnigan LLC) with ID–CUBE source (IonSense, Inc.). Capillary temperature was 200\textdegree C, and the capillary voltage was set to 15V in positive-ion mode. Helium was used as the ionization gas. Bruker Daltonics Omnimex MALDI–TOF mass spectrometer was also used for mass determination. The matrix was prepared following a literature procedure [49], containing 7,7,8,8-tetracyanoquinodimethane in THF (10 mg/mL) with 1 % silver trifluoroacetate as a promoter. Molecules were dissolved in THF to 0.1 mg/mL concentration and the solution (2 µL) was mixed with matrix (20 µL). UV–Vis absorption spectra were obtained using Agilent 8453 diode-array spectrophotometer.
Electrochemical measurements were carried out in a glove box under nitrogen, using an Autolab PGSTAT 10 or PGSTAT 20 potentiostat (Eco Chemie) in a three-electrode cell configuration. A Pt button (1.6 mm in diameter) electrode, a Pt wire, and a quasi-internal Ag wire submerged in 0.01M AgNO₃/0.1M tetrabutylammonium hexafluorophosphate (TBAPF₆) in acetonitrile were used as a working electrode, a counter electrode, and a reference electrode, respectively, in 0.1M TBAPF₆ toluene/acetonitrile (4:1) solution. The ferrocene/ferrocenium (Fc/Fc⁺) redox couple was used as an internal standard, with the half-wave potentials observed between 0.195–0.203 V vs Ag/Ag⁺ in toluene/acetonitrile (4:1) solution. Differential Scanning Calorimetry (DSC) was measured on a TA Instruments Q1000 DSC at scan rate of 10° C/min over the range of 25° C to 200° C or 35° C to 200° C. Thermogravimetric Analyses were performed with a TGA Q50 apparatus (TA Instruments) under nitrogen. Samples were heated at 10° C/min from 30° C to 800° C. X-ray diffraction was measured using Cu Kα radiation on an Inel CPS 120 position-sensitive detector with a XRG 3000 generator using aluminum substrate during ca. 20 minute collection time. Gaussian 03 software package was used for the structure optimization and the frequency calculation at the DFT level. B3LYP functional/6-31G (d,p) basis set was used for the computation.

**Syntheses of TMCB-Mono and TMCB-Bis.** In a flame dried 100 mL Schlenk flask, AlCl₃ (148 mg, 1.11 mmol) was dissolved in dry o-dichlorobenzene (o-DCB) (10 mL) and stirred at 0 °C under Ar. 2-Butyne (174 μL, 2.22 mmol) was added to the solution dropwise, and then o-DCB solution (20 mL) of C₆₀ (400 mg, 0.555 mmol) was added. After 1 hour of stirring to ensure formation of homogeneous phase, DMSO (0.2 mL, 2.33 mmol) was added dropwise and the solution was slowly warmed up to room temperature. Ethanol (50 mL) was poured, and the
precipitate was filtered and washed with ethanol several times, and then dissolved in toluene/hexane (1:1, 100 mL). The solution was passed through silica gel pad (5 cm), and concentrated in vacuo. Monoadduct and Bisadduct were separated by 5PBB Cosmosil column in toluene (4 mL/min) with yields of 31.9 % (146.6 mg) and 16.5 % (86.0 mg), respectively.

TMCB-Mono $^1$H NMR (500 MHz, CDCl$_3$, $\delta$): 2.07 (s, 6H), 1.97 (s, 6H). $^{13}$C NMR (500 MHz, CDCl$_3$, $\delta$): 154.62 (2C), 154.21 (2C), 147.24 (2C), 146.94 (2C), 146.91 (2C), 146.22 (2C), 146.14 (2C), 146.06 (2C), 145.53 (2C), 145.46 (2C), 145.39 (2C), 145.37 (2C), 145.35 (2C), 145.26 (2C), 144.69 (2C), 144.58 (2C), 143.21 (2C), 143.05 (2C), 142.79 (2C), 142.49 (2C), 142.35 (2C), 142.31 (2C), 142.25 (2C), 142.11 (2C), 140.43 (2C), 140.37 (2C), 139.06 (2C), 137.75 (2C), 129.22 (1C), 128.41 (1C), 74.38 (2C), 60.38 (2C), 53.62 (CH$_2$Cl$_2$), 14.07 (2C), 11.56 (2C).

HRMS (ESI, m/z): Monoadduct [M+H]^+ calcd for C_{68}H_{12}; 829.1012; found, 829.04, Bisadduct [M]^+ calcd for C_{76}H_{24}, 937.0060; found, 936.99

**Synthesis of TMCB-Tris.** In a flame dried 200 mL Schlenk flask, AlCl₃ (741 mg, 5.56 mmol) was dissolved in dry o-DCB (25 mL) and stirred at 0°C under Ar. 2-Butyne (0.88 mL, 11.1 mmol) was added to the solution dropwise, and then o-DCB solution (50 mL) of C₆₀ (1.0 g, 1.39 mmol) was added. After 1 hour of stirring, DMSO (0.89 mL, 11.4 mmol) was added dropwise and the solution was slowly warmed up to room temperature. Ethanol (100 mL) was poured, and the precipitate was filtered and washed with ethanol several times, and then dissolved in toluene/hexane (1:1, 250 mL). The solution was passed through silica gel pad (5 cm), and concentrated in vacuo. 115 mg (7.9 %) of the product was obtained after purification by 5PBB Cosmosil column in toluene (4 mL/min). \(^1\)H NMR (500 MHz, CDCl₃, δ): 2.16-1.57 (m, 36H). \(^1^3\)C NMR (500 MHz, CDCl₃, δ): 157.81 (2C), 157.68 (2C), 157.61 (2C), 155.49 (2C), 155.20 (2C), 155.09 (2C), 154.94 (2C), 154.57 (2C), 152.81 (2C), 151.51 (2C), 151.11 (2C), 149.70 (2C), 149.64 (2C), 149.57 (2C), 149.52 (2C), 149.45 (2C), 149.06 (2C), 148.94 (2C), 144.54 (2C), 144.84 (2C), 144.26 (2C), 144.23 (2C), 115.33 (2C), 115.18 (2C), 114.84 (2C), 114.73 (2C), 99.99 (2C), 59.90 (6C), 59.29 (6C), 29.91 (6C), 14.15 (2C), 13.86 (2C), 13.77 (2C), 11.65 (2C), 11.41 (2C), 11.36 (2C).

HRMS (MALDI–TOF, m/z): [M]^+ calcd for C_{84}H_{36}O_{10}, 1045.1871; found, 1045.22

**Synthesis of TMCB-Ep.** TMCB-Mono (102mg, 0.123mmol) was dissolved in chloroform (15 mL) in a 50 mL round-bottom flask in which a solution of 3-chloroperbenzoic acid (max. 77 % purity, 76 mg, 0.339 mmol) in chloroform (5 mL) was added dropwise at 0 °C. The solution was
slowly warmed up to room temperature during 7 hours of stirring, and a major product spot was 
detected on a TLC plate. The reaction mixture was diluted with dichloromethane (75 mL), and 
extracted with NaOH aqueous solution several times. The organic layer was dried with MgSO₄ 
and concentrated in vacuo. 100 mg (96.1 %) of the product was isolated after gradient silica 
column with 1:13 to 1:1 toluene/hexane eluent.

$^1$H NMR (500 MHz, CDCl₃, δ): 1.98 (s, 6H), 1.87 (s, 6H). $^{13}$C NMR (500 MHz, CDCl₃, δ):
153.77 (2C), 153.69 (2C), 147.20 (2C), 146.76 (2C), 146.57 (2C), 146.30 (2C), 146.22 (2C),
146.21 (4C), 145.69 (1C), 145.55 (2C), 145.51 (2C), 145.43 (1C), 145.39 (2C), 144.75 (2C),
144.70 (2C), 143.35 (1C), 143.34 (1C), 142.94 (2C), 142.90 (2C), 142.55 (2C), 142.49 (2C),

HRMS (ESI, m/z): [M+H]$^+$ calcd for C₆₈H₁₂O, 845.0961; found, 845.12

Syntheses of TBCB-Mono and TBCB-Bis. In a flame dried 50 mL Schlenk flask, AlCl₃ (150 mg,
1.12 mmol) was dissolved in dry o-DCB (15 mL) and stirred at 0°C under Ar. 5-Decyne (0.41
mL, 2.28 mmol) was added to the solution dropwise, and then o-DCB solution (50 mL) of C₆₀
(200 mg, 0.28 mmol) was added. After 1 hour of stirring, DMSO (0.2 mL, 2.33 mmol) was
added dropwise and the solution was slowly warmed up to room temperature. Ethanol (35 mL)
was poured, and the precipitate was filtered and washed with ethanol several times, and then
dissolved in toluene/hexane (1:4, 150 mL). The solution was passed through silica gel pad (5 cm),
and concentrated in vacuo. Monoadduct and Bisadduct were separated by 5PBB Cosmosil
column in toluene (4 mL/min) with yields of 40.1 % (111.1 mg) and 24.1 % (85.1 mg),
respectively. 17.7 % (35.5 mg) of C₆₀ was recovered.
TBCB-Mono $^1$H NMR (500 MHz, CDCl$_3$/CS$_2$ 1:1, δ): 2.69-2.63 (m, 4H), 2.47-2.41 (m, 2H), 2.30-2.24 (m, 2H), 2.02-1.98 (m, 2H), 1.91-1.73 (m, 6H), 1.54-1.50 (m, 8H), 1.04-1.01 (t, 12H).

$^{13}$C NMR (500 MHz, CDCl$_3$/CS$_2$ 1:1, δ): 155.19 (2C), 153.81 (2C), 149.58 (2C), 147.25 (2C), 146.71 (2C), 146.23 (2C), 146.06 (2C), 145.99 (2C), 145.96 (2C), 146.87 (2C), 145.33 (2C), 145.18 (2C), 145.16 (2C), 144.53 (2C), 144.41 (2C), 143.08 (2C), 143.03 (1C), 142.89 (1C), 142.74 (2C), 142.71 (2C), 142.62 (2C), 142.31 (2C), 142.19 (2C), 142.09 (2C), 142.08 (2C), 141.95 (2C), 140.30 (2C), 140.09 (2C), 138.77 (2C), 137.78 (2C), 73.98(2C), 64.00 (4C), 31.46 (2C), 31.43 (2C), 29.51 (2C), 28.90 (2C), 24.34 (2C), 23.83 (2C), 14.31 (2C), 14.28 (2C).

TBCB-Bis $^1$H NMR (500 MHz, CDCl$_3$/CS$_2$ 1:1, δ): 2.55-1.34 (m, 42H), 1.01-0.90 (m, 24H). $^{13}$C NMR (500 MHz, CDCl$_3$/CS$_2$ 1:1, δ): 157.71 (2C), 157.67 (2C), 156.63 (2C), 155.55 (2C), 154.62 (2C), 154.05 (2C), 153.75 (2C), 153.56 (2C), 152.15 (2C), 149.32 (2C), 148.98 (2C), 148.87 (2C), 148.47 (2C), 147.69 (2C), 147.11 (2C), 146.16 (2C), 145.00 (2C), 144.90 (2C), 144.85 (2C), 144.41 (2C), 144.27 (2C), 143.61 (2C), 142.57 (2C), 141.21 (2C), 141.14 (2C), 139.55 (2C), 138.83 (2C), 137.31 (2C), 63.55 (2C), 63.54 (2C), 31.40 (2C), 31.37 (2C), 31.26 (2C), 31.19 (2C), 30.03 (2C), 29.50 (2C), 29.38 (2C), 28.92 (2C), 28.87 (2C), 28.72 (2C), 24.56 (2C), 24.38 (2C), 24.30 (2C), 23.83 (2C), 23.71 (2C), 23.65 (2C), 14.37 (2C), 14.32 (2C), 14.28 (2C), 14.19 (2C).

Device Fabrication. Pre-patterned indium tin oxide (ITO)-coated glass substrates (Thin Film Devices, Inc.) were sonicated in acetone (30 min) and isopropanol (30 min) and oxygen plasma-cleaned (3 min) immediately prior to deposition of the PEDOT:PSS layer. PEDOT:PSS (2–5
wt% in water, Aldrich) was spin-coated in a nitrogen atmosphere at 4000 rpm and annealed at 150°C (using a hotplate) for 15 min under nitrogen. A 40 nm PEDOT layer was thus obtained. Film thickness was determined by ellipsometry measurements on separate films prepared on silicon substrates. For the active layer, a 10 mg/mL solution of 1:1.2 P3HT:fullerene in 1,2-dichlorobenzene (DCB) was employed (in a representative example, P3HT (1.9 mg) and fullerene (2.3 mg) were dissolved in DCB (0.2 mL)). This solution (60 μL) was then spin-coated onto the PEDOT layer at 1000 rpm under nitrogen. The substrate was taken from the spin chuck and immediately placed under an inverted Petri dish inside the glovebox for 10 minutes to encourage solvent annealing from the small amount of residual DCB on the substrate. Next, the solar cells were placed on a 150 °C hotplate and annealed for 20 min under nitrogen. A 70 ± 5 nm active layer was thus obtained. Following this deposition procedure, the top electrode was deposited by thermal evaporation of a 25 nm thick film of Ca followed by 80 nm thick film of Al. The device area, as defined by the anode-cathode overlap, is 1.21 mm².

**Device Characterization.** Current density–voltage (J–V) measurements were recorded by a Keithley 6487 picoammeter both in the dark and under illumination. The devices were illuminated through the glass substrate using an Oriel 91191 150 W full spectrum solar simulator. The illumination intensity was calibrated to 100 mW/cm² using an NREL-certified silicon photodiode. Spectral mismatch was not corrected for in these measurements.

**FET electron mobility measurement.** Bottom-gate, bottom-contact FETs were made on Si substrates with a thermally-grown SiO₂ layer (500 nm) and 10 μm channel lengths. (PCBM and
Top-gate, bottom-contact FETs were made on glass substrates with a PMMA layer (465 nm) top gate and 10 \( \mu \text{m} \) channel lengths. (TMCB-bis and TMCB-tris)

**Cofacial π-orbital interactions** between the fullerene and the cyclobutene addend are shown to decrease the electron affinity and thereby increase the LUMO energy level of C$_{60}$ significantly. The increased LUMO level of fullerene can be used to generate higher open-circuit voltages and a comparable power conversion efficiency relative to the widely used P3HT/PCBM composite.

2. Thermogravimetric Analysis (TGA)

Figure S2. TGA analysis of TMCB- and TBCB-adducts with scan rate of 10° C/min from 30° C to 800° C. Temperature of 5% weight loss of each compound is 223.4° C (TMCB-Mono), 326.0° C (TBCB-Mono), 274.7° C (TMCB-Bis and TBCB-Bis), and 424.4° C (TMCB-Tris). At 150° C, a typical annealing temperature of BHJ PSC fabrication, all compounds show reasonable thermal stabilities.
3. Differential Scanning Calorimetry (DSC) Characteristics

Figure S3. (a) First Cycle of TMCB-Mono, Bis, and Tris

(b) Second Cycle of TMCB-Mono, Bis, and Tris
(c) First Cycle of TBCB-Mono and Bis

![Graph showing heat flow vs. temperature for TBCB-Mono and TBCB-Bis.

(d) Second Cycle of TBCB-Mono and Bis

![Graph showing heat flow vs. temperature for TBCB-Mono and TBCB-Bis.

All the heat flows were measured at the scan rate of 10° C/min over the range from 25° C or 35° C to 200° C. Curves from the second to the fifth cycle were identical without any endothermic/exothermic features.
4. $^1$H NMR Spectra of Annealed TMCB-Multiadducts after 3 DSC Cycles

Figure S4. (a) TMCB-Bis Annealed

Red dots correspond to the peaks of TMCB-Mono, and blue dots to TMCB-Bis. The gained features after annealing indicate the thermal decomposition of the multiadducts to less-functionalized adducts.
5. X-ray Powder Diffraction Experiment of TMCB and TBCB Adducts.

Figure S5. (a) TMCB-Mono and Bis

(b) TBCB-Mono and Bis
Decreased 20 values of the monoadducts from C_{60} indicate their larger lattice constants in the microcrystalline phase, and the bisadducts are amorphous due to the presence of the multiple regioisomers. Annealing does not affect the crystallinity of TMCB-Bis.
6. J–V Characteristics of Bulk Heterojunction PSCs under Illumination

Figure S6. P3HT Blend with TBCB-Mono and Bis after Annealing at 90º C or 120º C
7. DFT Level Computation Results

Figure S7. (a) The Optimized Structure of TMCB-Mono (Ball-Bonds and Tube Representations) Determined at B3LYP/6-31G(d,p) Level of DFT Calculation

Angle between two four-membered rings ($\theta$) 113.4°

(b) The Optimized Structure of TMCB-Ep ($\theta = 114.5°$)
8. Molecular Orbital (MO) Energy Level Diagram and Isosurface Representations of Frontier Molecular Orbitals (HOMO-1, HOMO, LUMO, LUMO+1, and LUMO+2)

Figure S8. (a) TMCB-Mono

LUMO is shown in a side view and a front view for clearer comprehension.
(b) TMCB-Ep

LUMO+2 and HOMO are shown in a side view and a front view for clearer comprehension.
9. Syntheses of Tetraalkylcyclobutadiene–C$_{60}$ Adducts

Scheme S1. AlCl$_3$-Assisted Diels–Alder Cycloaddition Reactions between C$_{60}$ and 3-Hexyne, 4-Octyne, and 5-Decyne
