Observation of $B^0_s \to J/\psi f_1(1285)$ Decays and Measurement of the $f_1(1285)$ Mixing Angle

R. Aaij et al. (*
(LHCb Collaboration)
(Received 8 October 2013; published 4 March 2014)

Decays of $B^0_s$ and $B^0_s$ mesons into $J/\psi \pi^+\pi^-\pi^+\pi^-$ final states, produced in $pp$ collisions at the LHC, are investigated using data corresponding to an integrated luminosity of 3 fb$^{-1}$ collected with the LHCb detector. $B^0_s \to J/\psi f_1(1285)$ decays are seen for the first time, and the branching fractions are measured. Using these rates, the $f_1(1285)$ mixing angle between strange and nonstrange components of its wave function in the $q\bar{q}$ structure model is determined to be $(24.0^{+3.1+0.6}_{-2.5-0.9})^\circ$. Implications on the possible tetraquark nature of the $f_1(1285)$ are discussed.

Light flavorless hadrons, $f$, are not entirely understood as $q\bar{q}$ states. Some states with the same quantum numbers such as the $\eta$ and $\eta'$ exhibit mixing [1]. Others, such as the $f_0(500)$ and the $f_0(980)$, could be mixed $q\bar{q}$ states, or they could be comprised of tetraquarks [2]. In addition, some states, such as the $f_0(1500)$, are discussed as being made solely of gluons [3]. Understanding if the $f$ states are indeed explained by the quark model is crucial to identifying other exotic structures. Previous investigations of $B^0_s$ and $\bar{B}^0$ decays (called generically $\bar{B}$) into a $J/\psi$ meson and a $\pi^+\pi^-$ [4,5] or $K^+K^-$ [6,7] pair have revealed the presence of several light flavorless meson resonances including the $f_0(500)$ and the $f_0(980)$. Use of $\bar{B} \to J/\psi f$ decays has been suggested as an excellent way of both measuring mixing angles and discerning if some of the $f$ states are tetraquarks [8,9]. In this Letter the $J/\psi \pi^+\pi^-\pi^+\pi^-$ final state is investigated with the aim of seeking additional $f$ states. (Mention of a particular process also implies the use of its charge conjugated decay.)

Data are obtained from 3 fb$^{-1}$ of integrated luminosity collected with the LHCb detector [10] using $pp$ collisions. One third of the data was acquired at a center-of-mass energy of 7 TeV, and the remainder at 8 TeV. The LHCb detector is a single-arm forward spectrometer covering the pseudorapidity range $2 < \eta < 5$, designed for the study of particles containing $b$ or $c$ quarks. The detector includes a high precision tracking system consisting of a silicon-strip vertex detector surrounding the $pp$ interaction region, a large-area silicon-strip detector located upstream of a dipole magnet with a bending power of about 4 Tm, and three stations of silicon-strip detectors and straw drift tubes placed downstream. The combined tracking system provides a momentum measurement with relative uncertainty that varies from 0.4% at 5 GeV to 0.6% at 100 GeV. (We work in units where $c = 1$.) The impact parameter (IP) is defined as the minimum track distance with respect to the primary vertex. For tracks with large transverse momentum, $p_T$, with respect to the proton beam direction, the IP resolution is approximately 20 $\mu$m. Charged hadrons are identified using two ring-imaging Cherenkov (RICH) detectors. Photon, electron, and hadron candidates are identified by a calorimeter system consisting of scintillating-pad and preshower detectors, an electromagnetic calorimeter, and a hadronic calorimeter. Muons are identified by a system composed of alternating layers of iron and multiwire proportional chambers.

The LHCb trigger [11] consists of a hardware stage, based on information from the calorimeter and muon systems, followed by a software stage that applies event reconstruction. Events selected for this analysis are triggered by a candidate $J/\psi \to \mu^+\mu^-$ decay, required to be consistent with coming from the decay of a $b$ hadron by using either IP requirements or detachment from the associated primary vertex. Simulations are performed using PYTHIA [12] with the specific tuning given in Ref. [13], and the LHCb detector description based on GEANT4 [14] described in Ref. [15]. Decays of $b$ hadrons are based on EVTGEN [16].

Events are preselected and then are further filtered using a multivariate analyzer based on the boosted decision tree (BDT) technique [17]. In the preselection, all charged track candidates are required to have $p_T > 250$ MeV, while for muon candidates the requirement is $p_T > 550$ MeV. Events must have a $\mu^+\mu^-$ combination that forms a common vertex with $\chi^2 < 20$, an invariant mass between $-48$ and $+43$ MeV of the $J/\psi$ meson mass, and are constrained to the $J/\psi$ mass. The four pions must have a vector summed $p_T > 1.0$ GeV, form a vertex with $\chi^2 < 50$ for 5 degrees of freedom, and a common vertex with the
$J/\psi$ candidate with $\chi^2 < 90$ for 9 degrees of freedom. The angle between the $B$ momentum and the vector from the primary vertex to the $B$ decay vertex is required to be smaller than 2.56°. Particle identification [18] requirements are based on the difference in the logarithm of the likelihood, DLL($h_1 - h_2$), to distinguish between the hypotheses $h_1$ and $h_2$. We require DLL($\pi - \mu$) $> -10$ and DLL($\pi - K$) $> -10$. We also explicitly eliminate candidate $\psi(2S) [X(3872)] \rightarrow J/\psi \pi^+ \pi^-$ events by rejecting any candidate where one $J/\psi \pi^+ \pi^-$ combination is within 23 MeV of the $\psi(2S)$ or 9 MeV of the $X(3872)$ meson masses. Other resonant contributions such as $B \rightarrow \psi(4160)\pi^+ \pi^-$ are searched for, but not found.

The BDT uses 12 variables that are chosen to separate signal and background: the minimum DLL($\pi - \mu$) of the $\mu^+$ and $\mu^-$, the scalar $p_T$ sum of the four pions, and the vector $p_T$ sum of the four pions; relating to the $B$ candidate: the flight distance, the vertex $\chi^2$, the $p_T$, and the $\chi^2_{IP}$, which is defined as the difference in $\chi^2$ of a given primary vertex reconstructed with and without the considered particle. In addition, considering the $\pi^+ \pi^+$ and $\pi^- \pi^-$ as pairs of particles, the minimum $p_T$, and the minimum $\chi^2_{IP}$ of each pair are used. The signal sample used for BDT training is based on simulation, while the background sample uses the sideband 200–250 MeV above the $B^0$ mass peak from 1/3 of the available data. The BDT is then tested on independent samples from the same sources. The BDT selection is optimized by taking the signal, $S$, and background, $B$, events within $\pm 20$ MeV of the $B^0$ peak from the preselection and maximizing $S^2/(S+B)$ by using the signal and background efficiencies provided as a function of BDT.

The $J/\psi \pi^+ \pi^- \pi^+ \pi^-$ invariant mass distribution is shown in Fig. 1. Multiple combinations are at the 6% level and a single candidate is chosen based on vertex $\chi^2$ and $J/\psi$ mass. We fit the mass distribution using the same signal function shape for both $B^0$ and $\bar{B}^0$ peaks. This shape is a double Crystal Ball function [19] with common means and radiative tail parameters obtained from simulation. The combinatorial background is parametrized with an exponential function. There are 1193 $\pm$ 46 $B^0$ and 839 $\pm$ 39 $\bar{B}^0$ decays. Possible backgrounds caused by particle misidentification, for example $\bar{B}^0 \rightarrow J/\psi \pi^+ K^- \pi^+ \pi^-$ decays, would appear as signal if the particle identification incorrectly assigns the $K^-$ as a $\pi^-$. In this case the invariant mass is always below the $B^0$ signal region. Evaluating all such backgrounds shows negligible contributions in the signal regions. These and other low-mass backgrounds are described by a Gaussian distribution.

In order to improve the four-pion mass resolution we kinematically fit each candidate with the constraints that the $\mu^+ \mu^-$ be at the $J/\psi$ mass and that the $J/\psi \pi^+ \pi^- \pi^+ \pi^-$ be at the $B$ mass. The four-pion invariant mass distributions for $B^0$ and $\bar{B}^0$ decays within $\pm 20$ MeV of the $B$ mass peaks are shown in Fig. 2. The backgrounds, determined from fits to the number of events in the region 40–80 MeV above the $B^0$ mass, are subtracted.

There are clear signals around 1285 MeV in both $B^0$ and $\bar{B}^0$ decays with structures at higher masses. The $J/\psi$ decay angular distribution is used to probe the spin of the recoiling four-pion system. We examine the distribution of the helicity angle $\theta$ of the $\mu^+$ with respect to the $B$ direction in the $J/\psi$ rest frame, after correcting for the angular acceptance using simulation. The resulting distribution is then fit by the sum of shapes $(1 - \alpha)\sin^2\theta$ and $\alpha(1 + \cos^2\theta)/2$, where $\alpha$ is the fraction of the helicity $\pm 1$ component. For scalar four-pion states the $J/\psi$ helicity is 0, while for higher spin states it is a mixture of helicity 0 and helicity $\pm 1$ components. We also show in Fig. 2 the helicity $\pm 1$ yields. In the region near 1285 MeV there is a significant helicity $\pm 1$ component, as expected if the state we are observing is the $f_1(1285)$.

There is also a large and wider peak near 1450 MeV in the $B^0$ channel. Previously we observed a structure at a mass near 1475 MeV using $B^0 \rightarrow J/\psi \pi^+ \pi^-$ decays that we attributed to $f_0(1370)$ decay. However, it could equally well be the $f_0(1500)$ meson, an interpretation favored by Ochs [3]. While the $f_0(1500)$ is known to decay into four pions, the structure observed in our data cannot be pure spin 0 because of the significant helicity $\pm 1$ component in this mass region. We do not pursue further the composition of the higher mass regions in either $B^0$ or $\bar{B}^0$ decays in this Letter.

We use the measured branching fractions of $B^0 \rightarrow J/\psi \pi^+ \pi^- $ [4] and $B^0 \rightarrow J/\psi \pi^+ \pi^- $ [5] for normalizations. The data selection is updated from that used in previous publications to more closely follow the procedure in this analysis. We find signal yields of 22,476 $\pm$ 177 $B^0$ events and 16,016 $\pm$ 187 $\bar{B}^0$ events within $\pm 20$ MeV of the signal.
The overall efficiencies determined by simulation are $(1.411 \pm 0.015)\%$ and $(1.317 \pm 0.015)\%$, respectively, for $B^0_s$ and $B^0$ decays, where the uncertainty is statistical only. The relative efficiencies for the $J/\psi ^+\pi ^+\pi ^-\pi ^+$ final states with respect to $J/\psi ^+\pi ^-$ are $14.3\%$ and $14.5\%$ for $B^0_s$ and $B^0$ decays, with small statistical uncertainties. We compute the overall branching fraction ratios

$$\frac{B(B^0_s \to J/\psi ^+\pi ^+\pi ^-\pi ^-)}{B(B^0 \to J/\psi ^+\pi ^-)} = 0.371 \pm 0.015 \pm 0.022,$$

$$\frac{B(B^0 \to J/\psi ^+\pi ^+\pi ^-\pi ^-)}{B(B^0 \to J/\psi ^+\pi ^-)} = 0.361 \pm 0.017 \pm 0.021.$$ 

The systematic uncertainties arise from the decay model (5.0%), background shape (0.8%), signal shape (0.8%), simulation statistics (1.9%), and tracking efficiencies (2.0%), resulting in a total of 5.8%.

We proceed to determine the $J/\psi f_1(1285)$ yields by fitting the individual four-pion mass spectra in both $B^0_s$ and $B^0$ final states. The $f_1(1285)$ state is modeled by a relativistic Breit-Wigner function multiplied by phase space and convoluted with our mass resolution of 3 MeV. We take the mass and width of the $f_1(1285)$ as $1282.1 \pm 0.6$ MeV and $24.2 \pm 1.1$ MeV, respectively [1]. The combinatorial background is constrained from sideband data and is allowed to vary by its statistical uncertainty. Backgrounds from higher mass resonances are parametrized by Gaussian shapes whose masses and widths are allowed to vary. We restrict the fits to the interval $1.1$–$1.5$ GeV, which contains 94.3% of the signal. The fits to the data are shown in Fig. 3. The results of the fits are listed in Table I along with twice the negative change in the logarithm of the likelihood $(-2\Delta \ln L)$ if fit without the signal, and the resulting signal significance. The systematic uncertainties from the signal shape and higher mass resonances have been included. Both final states are seen with significance above five standard deviations. This constitutes the first observation of the

![FIG. 2](color online). Background subtracted invariant mass distributions of the four pions in (a) $B^0_s$ and (b) $B^0$ decays are shown in the histogram overlaid with the (black) solid points with the error bars indicating the uncertainties. The open (red) circles show the helicity $\pm 1$ components of the signals.

![FIG. 3](color online). Fits to the four-pion invariant mass in (a) $B^0_s$ and (b) $B^0$ decays. The data are shown as points, the signals components as (black) dashed curves, the combinatorial background by (black) dotted curves, and the higher mass resonance tail by (red) dot-dashed curves.
$f_1(1250)$ in $b$-hadron decays. As a consistency check, we also perform a simultaneous fit to both $\bar{B}_s^0$ and $B^0$ samples letting the mass and width vary in the fit. We find the

$$
\frac{\mathcal{B}(\bar{B}_s^0 \to J/\psi f_1(1250), f_1(1250) \to \pi^+ \pi^- \pi^+) \mathcal{B}(\bar{B}_s^0 \to J/\psi \pi^+ \pi^-)}{\mathcal{B}(\bar{B}_s^0 \to J/\psi \pi^+ \pi^-)} = (3.82 \pm 0.52^{+0.29}_{-0.32})\%,
$$

For the latter ratio we use a $\bar{B}_s^0/B^0$ production ratio of $0.259 \pm 0.015$ [20]; this uncertainty is taken as systematic. The other systematic uncertainties are listed in Table II. The shape of the high-mass tail is changed in the case of $\bar{B}_s^0$ decays from a single Gaussian to two relativistic Breit-Wigner shapes corresponding to the mass and width values of the $f_1(1420)$ and the $f_0(1500)$ mesons. For the $\bar{B}_s^0$ high mass shape we change from a Gaussian shape to a second order polynomial. The decay model reflects the allowed variation in the fraction of $\bar{B}_s^0/B^0$ and $\bar{B}_s^0/\pi^+ \pi^-$ decays. The total uncertainties are ascertained by adding the individual components in quadrature separately for the positive and negative values.

Considering the $f_1(1250)$ as a mixed $q\bar{q}b$ state, we characterize the mixing with a $2 \times 2$ rotation matrix containing a single parameter, the angle $\phi$, so that the wave functions of the $f_1(1250)$ and its partner, indicated by $f_1^*$, are given by

$$
|f_1(1250)\rangle = \cos \phi |n\bar{n}\rangle - \sin \phi |s\bar{s}\rangle,
$$

$$
|f_1^*(1250)\rangle = \sin \phi |n\bar{n}\rangle + \cos \phi |s\bar{s}\rangle,
$$

where $|n\bar{n}\rangle \equiv \frac{1}{\sqrt{2}}(|u\bar{u}\rangle + |d\bar{d}\rangle).$ (1)

The decay widths can be written as [8]

$$
\Gamma(\bar{B}_s^0 \to J/\psi f_1(1250)) = 0.5|A_0|^2|V_{cd}|^2\Phi_0 \cos^2 \phi,
$$

$$
\Gamma(\bar{B}_s^0 \to J/\psi f_1(1250)) = |A_1|^2|V_{cs}|^2\Phi_1 \sin^2 \phi,
$$

where $A_i$ is the tree level amplitude, $V_{cd}$ and $V_{cs}$ are quark mixing matrix elements, and $\Phi_i$ are phase space factors. The amplitude ratio $|A_0|/|A_1|$ is taken as unity [8]. The width ratio is given by

$$
\frac{\mathcal{B}(\bar{B}_s^0 \to J/\psi f_1(1250))}{\mathcal{B}(\bar{B}_s^0 \to J/\psi f_1(1250))} = \frac{\tau_0 |V_{cd}|^2 \Phi_0 \cos^2 \phi}{2 \tau_s |V_{cs}|^2 \Phi_1 \sin^2 \phi},
$$

where $\tau_s$ is the $B_s^0$ lifetime and $\tau_0$ is the $B^0$ lifetime. The angle $\phi$ is then given by

$$
\tan^2 \phi = 1 \frac{\mathcal{B}(\bar{B}_s^0 \to J/\psi f_1(1250))}{\mathcal{B}(\bar{B}_s^0 \to J/\psi f_1(1250))} \frac{\tau_0 |V_{cd}|^2 \Phi_0}{2 \tau_s |V_{cs}|^2 \Phi_1}
$$

$$
= 0.1970 \pm 0.053^{+0.04}_{-0.012}.
$$

The ratio of the phase space factors $\Phi_0/\Phi_1$ equals 0.855. The other input values are $\tau_s = 1.508$ ps [21], $\tau_0 = 1.519$ ps, $|V_{cd}| = 0.2245$, and $|V_{cs}| = 0.97345$ [1]. We use the lifetime measured in $\bar{B}_s^0 \to J/\psi \phi$ decays as the helicity components are in approximately the same ratio as in $J/\psi f_1(1250)$. No uncertainties are assigned on these

It to be produced significantly in both $B^0_s$ and $B^0$ decays into $J/\psi f_1(1285)$. Using this wave function, the tetraquark model described in Ref. [8] predicts

$$\frac{B(B^0_s \to J/\psi f_1(1285))}{B(B^0 \to J/\psi f_1(1285))} = \frac{\tau_0}{4 \tau_s} |V_{cs}|^2 = 1.14\%,$$

with small uncertainties. Our measurement of this ratio of $(11.6 \pm 3.1_{-0.8}^{+0.7})\%$ differs by 3.3 standard deviations from the tetraquark interpretation including the systematic uncertainty.

Branching fraction ratios are converted into branching fractions using the previously measured rates listed in Table III. We correct the $B^0_s$ rates to reflect the updated value of the $B^0_s$ to $B^0$ production fraction of $0.259 \pm 0.015$ [20]. We determine

$$\frac{B(B^0_s \to J/\psi f_1(1285))}{B(B^0 \to J/\psi f_1(1285))} = (7.62 \pm 0.36 \pm 0.64 \pm 0.42) \times 10^{-5},$$

$$\frac{B(B^0_s \to J/\psi f_1(1285))}{B(B^0 \to J/\psi f_1(1285))} = (1.43 \pm 0.08 \pm 0.09 \pm 0.06) \times 10^{-5},$$

where the first uncertainty is statistical, the second and third are systematic, being due to the relative branching fraction measurements and the errors in the absolute branching fraction normalization, respectively. For the $B^0_s$ decay this normalization error is due to the uncertainty on the production ratio of $B^0_s$ versus $B^0$ and is $5.8\%$ [5]. For the $B^0$ mode the uncertainty is due to the error of $4.1\%$ on $B(B^- \to J/\psi K^-)$ [6].

In conclusion, we report the first observations of $B^0_s$ and $B^0 \to J/\psi f_1(1285)$ decays. These are also the first observations of the $f_1(1285)$ meson in heavy quark decays.

We express our gratitude to our colleagues in the CERN accelerator departments for the excellent performance of the LHC. We thank the technical and administrative staff at the LHCb institutes. We acknowledge support from CERN and from the national agencies CAPES, CNPq, FAPERJ, and FINEP (Brazil); NSFC (China); CNRS/IN2P3 and Region Auvergne (France); BMBF, DFG, HGF, and MPG (Germany); SFI (Ireland); INFN (Italy); FOM and NWO (Netherlands); SCSR (Poland); MEN/IFA (Romania);
MinES, Rosatom, RFBR, and NRC “Kurchatov Institute” (Russia); MinECo, XuntaGal and GENCAT (Spain); SNSF and SER (Switzerland); NAS Ukraine (Ukraine); STFC (United Kingdom); NSF (USA). We also acknowledge the support received from the ERC under FP7. The Tier1 computing centres are supported by IN2P3 (France), KIT, and BMBF (Germany), INAF (Italy), NWO, and SURF (Netherlands), PIC (Spain), GridPP (United Kingdom). We are thankful for the computing resources put at our disposal by Yandex LLC (Russia), as well as to the communities behind the multiple open source software packages that we depend on.
