SUMMARY

Recognition of the proper start codon on mRNAs is essential for protein synthesis, which requires scanning and involves eukaryotic initiation factors (eIFs) eIF1, eIF1A, eIF2, and eIF5. The carboxyl terminal domain (CTD) of eIF5 stimulates 43S preinitiation complex (PIC) assembly; however, its precise role in scanning and start codon selection has remained unknown. Using nuclear magnetic resonance (NMR) spectroscopy, we identified the binding sites of eIF1 and eIF2β on eIF5-CTD and found that they partially overlapped. Mutating select eIF5 residues in the common interface specifically disrupts interaction with both factors. Genetic and biochemical evidence indicates that these eIF5-CTD mutations impair start codon recognition and impede eIF1 release from the PIC by abrogating eIF5-CTD binding to eIF2β. This study provides mechanistic insight into the role of eIF5-CTD’s dynamic interplay with eIF1 and eIF2β in switching PICs from an open to a closed state at start codons.

INTRODUCTION

To achieve accurate selection of the AUG start codon, the scanning preinitiation complex (PIC) is thought to exist in equilibrium between two conformations, mediated by initiation factors: open, scanning competent, and closed, scanning incompetent (Pestova and Kolupaeva, 2002). Recently, a crystal structure of the *Tetrahymena thermophila* 4OS subunit along with eukaryotic initiation factor (eIF1) was determined, which is strategically located near the P-site (Rabl et al., 2011) consistent with previous hydroxyl-radical footprinting studies (Lomakin et al., 2003). In this crystal structure, the head of the 40S in different space groups has been found in different conformations relative to the body. This may indeed be related to the two inferred states; however, the detailed mechanism of start codon recognition caused by the dynamic interplay of initiation factors with the mRNA and the ribosome will require additional investigations with a wide range of biophysical/biochemical methods along with validation in both in vitro and in vivo assays. Here, we seek to elucidate the mechanisms of start codon recognition.

Studies on yeast factors have suggested a model for initiation factor-mediated conformational changes of the ribosome during the process of scanning and start codon recognition (Asano and Sachs, 2007; Hinnebusch, 2011).

(1) eIF1 and eIF1A stabilize the open complex with Met-tRNA<sub>Met</sub> loaded on the P-site. Here, the globular part of eIF1A occupies the A-site, whereas its C-terminal tail (CTT) extends into the P-site (Yu et al., 2009), and eIF1 binds on the 40S next to the Met-tRNA<sub>Met</sub> (Lomakin et al., 2003).

(2) eIF5 induces the hydrolysis of GTP bound to eIF2 as a GTPase-activating protein (GAP) upon or subsequent to mRNA binding to the PIC; however, the resulting GDP and P<sub>i</sub> release is the rate-limiting step of the PIC in response to AUG selection.
(3) AUG recognition and tighter Met-tRNA<sup>Met</sup> binding trigger the transition to the closed state but require eIF1 dissociation and ejection of the CTT of eIF1A from the P-site.

(4) eIF1 dissociation enables gated release of P<sub>i</sub>, which effectively ends the scanning mechanism. The dissociation of eIF1 with concomitant P<sub>i</sub> release signifies the first irreversible step in translation initiation; hence, we asked whether eIF5-carboxyl terminal domain (CTD) serves a regulatory function in the ejection of eIF1 from PICs at start codons.

Capitalizing on different eIF1A dissociation kinetics between the open and closed states, individual mutations altering eIF1A or eIF5 (within its NTD [N-terminal domain]) were shown to manipulate the closed and open states of the AUG- or UUG-bound PIC (Maag et al., 2006). Any mutation that favors the closed PIC and allows initiation at a faulty UUG codon would promote translation initiation at the expense of lower fidelity, leading to a suppressor of initiation (Sui<sup>−</sup>) codon mutation phenotype, whereas a mutation that favors the open complex and blocks faulty initiation at a UUG codon would increase the fidelity of translation initiation, a suppressor of Sui<sup>−</sup> (Ssu<sup>−</sup>) phenotype (Saini et al., 2010). Thus, Sui<sup>−</sup> mutations stabilize the open state, whereas Ssu<sup>−</sup> mutations favor the open state of the PIC (summarized in Table S1 available online).

eIF5 is necessary for 60S ribosomal subunit joining, which is ultimately mediated by eIF5B and occurs only after start codon recognition and the cessation of scanning (Pestova et al., 2000). The best-characterized function of eIF5 is to serve, through its NTD (eIF5-NTD; residues 1–170), as the GAP for the eIF2-TC (Conte et al., 2006), which is critical for start codon recognition. The CTD of eIF5 plays a role in assembly of the PIC by stabilizing interactions among eIF1, eIF2, and eIF3 in the recognition. The CTD of eIF5 is necessary for 60S ribosomal subunit joining, which is ultimately mediated by eIF5B and occurs only after start codon recognition and the cessation of scanning (Pestova et al., 2000). The best-characterized function of eIF5 is to serve, through its NTD (eIF5-NTD; residues 1–170), as the GAP for the eIF2-TC (Conte et al., 2006), which is critical for start codon recognition. The CTD of eIF5 plays a role in assembly of the PIC by stabilizing interactions among eIF1, eIF2, and eIF3 in the recognition. The CTD of eIF5 is necessary for 60S ribosomal subunit joining, which is ultimately mediated by eIF5B and occurs only after start codon recognition and the cessation of scanning (Pestova et al., 2000). The best-characterized function of eIF5 is to serve, through its NTD (eIF5-NTD; residues 1–170), as the GAP for the eIF2-TC (Conte et al., 2006), which is critical for start codon recognition. The CTD of eIF5 plays a role in assembly of the PIC by stabilizing interactions among eIF1, eIF2, and eIF3 in the recognition.
NMR (Figure S3A). We examined whether double mutations on the surface of eIF5-CTD affect eIF1 binding; however, we were not able to completely abrogate binding between human eIF1 and eIF5-CTD using any of these double mutations as detected by NMR (Figure S3B). These mutagenesis results are congruent with the model in Figure 1G.

The Unstructured N-Terminal Lysine-Rich Tail of eIF2β Binds eIF5-CTD at an Epitope Overlapped with the eIF1-Binding Site

eIF2β-NTD contains three stretches of lysines, named K1, K2, and K3 boxes (Figure 1A). A previous study employing a panel of human eIF2β mutant constructs clearly shows that the NTD of eIF2β is responsible for binding to 32P-labeled rat eIF5 used as a probe, wherein the K2 box of eIF2β was identified as the primary region for binding eIF5 (Das et al., 1997). Based on this finding, which we confirmed by NMR (Figures S4A–S4E), we produced a smaller eIF2β-NTD construct and named eIF2β-K2K3 (eIF2β residues 53–135; which contains the K2 and K3 boxes), and we mapped its binding surface on heIF5-CTD (Figures 1A, 2A, and 2B). Unlabeled eIF2β-K2K3 caused CSP and peak broadening of 15N-labeled eIF5-CTD residues (Figures 2C and 2D). We noticed that the region of eIF5-CTD affected by eIF2β-K2K3 binding overlaps the region affected by eIF1 (compare Figures 1B and 2A). The eIF5-CTD-Quad mutant exhibited a drastically reduced ability to bind eIF2β-K2K3, as evidenced by significantly smaller CSPs and less broadening than observed with eIF5-CTD-WT (compare Figures 2D and 2E).

Using ITC, we measured an equilibrium dissociation constant (Kd) for the eIF5-CTD:eIF2β-NTD interaction of ~17 μM.
The K_D for the eIF5-CTD interaction with the shorter eIF2β-K2K3 construct was measured as ~4 μM (Figure 3A).
The similar eIF5-CTD-binding affinities with eIF2β-NTD and eIF2β-K2K3 confirm the findings in a previous eIF2β:eIF5 interaction study by Das et al. (1997) and validate our decision to utilize the eIF2β-K2K3 construct for mapping its interaction with eIF5-CTD. A noticeable baseline deviation after saturation (Figures 3A and 3B) does not contribute significantly to the qualitative comparisons among differing eIF5-CTD complexes. We found that the eIF5-CTD-DD mutant:eIF2β-K2K3 interaction exhibits a similar affinity, also in the low micromolar range, with a K_D of ~8 μM (Figure 3B). In contrast, the binding affinity of eIF2β-K2K3 with either eIF5-CTD-KK or eIF5-CTD-Quad was abolished and could not be determined by ITC (data not shown), hence validating our NMR-chemical shift mapping data and substantiating the identification of a critical linkage between eIF5 and eIF2β.

**SAXS Reconstitution Assay Shows that eIF5-CTD Does Not Simultaneously Bind eIF2β and eIF1**
Because the eIF1:eIF5-CTD interaction could not be quantified by ITC measurements (data not shown), we employed SAXS (small-angle X-ray scattering). In this SAXS reconstitution assay, increasing amounts of eIF1 were titrated into a fixed concentration of eIF5-CTD, and the mixture at each point was subjected to X-ray analysis. The radius of gyration (R_g), being analogous to the

**Figure 2. The eIF2β-K2K3 Segment Contacts eIF5-CTD on a Site Partially Overlapped with the eIF1-Binding Face**
(A) eIF2β-K2K3-binding surface on eIF5-CTD. Two orientations are shown as surface representations; left orientation is the same as Figure 1B. Residues wherein eIF2β-K2K3 causes CSPs are painted red, those experiencing line broadening are painted yellow, and those seeing both effects are painted orange.
(B) eIF2β-K2K3-binding surface on eIF5-CTD depicted as ribbons; same orientation as left in (A).
(C) Schematic representation of the labeling scheme used in the proton-nitrogen correlation spectra: 15N-labeled eIF5-CTD is measured alone (residues 225–407) (circumscribed in a red box) and in the presence of unlabeled eIF2β-K2K3 (residues 53–135) (circumscribed in a blue box).
(D) Overlay of 1H-15N HSQC spectra of 0.2 mM 15N-labeled WT eIF5-CTD alone (red) and in the presence of 0.24 mM unlabeled eIF2β-K2K3 (blue).
(E) Overlay of 1H-15N HSQC spectra of 0.2 mM 15N-labeled eIF5-CTD-Quad mutant domain alone (red) and in the presence of 0.24 mM unlabeled eIF2β-K2K3 (blue).
See also Figure S4.
moment of inertia in mechanics, reflects the conformational/binding state of the proteins in solution, free or in complex with each other. Increasing the $\text{eIF1:}\text{eIF5-CTD}$ ratio results in a steady increase in the $R_g$, consistent with complex formation between $\text{eIF1}$ and $\text{eIF5-CTD}$ (Figure 3C, black spheres, and Figure S5 A). However, there is no saturation of the $R_g$ value, indicative of a weak-binding interaction between $\text{eIF1}$ and $\text{eIF5-CTD}$. Because $\text{eIF1}$ and $\text{eIF2β}$-NTD bind to overlapping surfaces on $\text{eIF5-CTD}$, we used the SAXS reconstitution assay to monitor whether these three proteins bind simultaneously to form a higher-order complex in solution. Upon the titration of $\text{eIF1}$ to a preformed $\text{eIF5-CTD:}\text{eIF2β}$-NTD complex, these three proteins do not form a higher-order complex under these conditions, as evidenced by the lack of an increase in the $R_g$ (Figure 3C, gray dots).

Figure 3. ITC and SAXS Narrow Down the $\text{eIF2β}$-Binding Site and Suggest Competitive Binding with $\text{eIF1}$
(A) ITC analysis of the $\text{eIF5-CTD:}\text{eIF2β}$K2K3 interaction. A solution of $\text{eIF2β}$K2K3 injected with $\text{eIF5-CTD}$ WT.
(B) ITC analysis of the $\text{eIF5-CTD}$-DD mutant:$\text{eIF2β}$K2K3 interaction. A solution of $\text{eIF2β}$K2K3 injected with $\text{eIF5-CTD}$-DD. Interestingly, the KK and/or Quad(DDKK) mutations of $\text{eIF5-CTD}$ abrogate binding to $\text{eIF2β}$.
(C and D) SAXS reconstitution assay used to monitor complex formations. Linear relation of the low-angle portion of the data corresponds to well-behaved proteins devoid of aggregation, even in samples with high concentration. (C) SAXS results plotting the $R_g$ versus $\text{eIF1:}\text{eIF5-CTD}$ (black) and $\text{eIF1:}(\text{eIF5-CTD+eIF2β}$-NTD) (gray) protein ratios. The data indicate that $\text{eIF1}$ binds $\text{eIF5-CTD}$ but does not displace $\text{eIF2β}$-NTD or form a heterotrimeric complex. (D) Scattering intensities, $I(0)$, shown as a function of concentration dependence; same protein samples as in (C). Plotting the scattering intensity ($y$ axis) versus $\text{eIF1:}(\text{eIF5-CTD+eIF2β}$-NTD) molar ratios ($x$ axis; gray line) shows a concentration dependence. The same was done for $\text{eIF1:}\text{eIF5-CTD}$ ratios (black lines). Data were collected for $\text{eIF5-CTD}$ (90 μM) titrated with increasing amounts of $\text{eIF1}$. $R_g$ serves as an indicator for the formation of higher-order protein complexes. SAXS results plotting the $R_g$ ($y$ axis) versus protein ratios ($x$ axis). Black circles indicate $\text{eIF5-CTD}$ (90 μM) titrated with increasing amounts of $\text{eIF1}$ (90, 180, 360, 540, 720, 900, 1,350, and 1,800 μM). Gray circles represent $\text{eIF5-CTD:}\text{eIF2β}$-NTD FPLC-purified complex (90 μM) titrated with increasing amounts of $\text{eIF1}$ (90, 450, and 1,620 μM). See also Figure S5.

Because $\text{eIF1}$ and $\text{eIF2β}$-NTD bind to overlapping surfaces on $\text{eIF5-CTD}$, we used the SAXS reconstitution assay to monitor whether these three proteins bind simultaneously to form a higher-order complex in solution. Upon the titration of $\text{eIF1}$ to a preformed $\text{eIF5-CTD:}\text{eIF2β}$-NTD complex, these three proteins do not form a higher-order complex under these conditions, as evidenced by the lack of an increase in the $R_g$ (Figure 3C, gray dots).
spheres, and Figure S5B). The protein ratios in Figure 3D are the same as in Figure 3C, wherein the increase in the number of scatterers (amount of proteins) is related to the linear increase in the SAXS intensity: I(0) (Figure 3D, black and gray spheres).

The Interaction between eIF1 and eIF5-CTD Is Evolutionarily Conserved

Upon deletion of the flexible NTT of eIF1, the body of eIF1 still makes contact with eIF5-CTD near residues H305 and N306; other residues showing effects include D344, E348 (in the turn between helices 8 and 7), Y362 (in the turn between helices 7 and 8), and E386 (in the long loop between helices 8 and 9) (Figures S5C and S5D). Thus, the NTT of human eIF1 plays an ancillary role in binding to eIF5. As previously mentioned, the eIF1-binding surface on eIF5-CTD maps to an overlapping surface wherein eIF2α also binds (Figure S5E), and the mutated Quad residues directly impact this overlapping region (Figure S5F). We proceeded to examine heterogeneous interactions by NMR spectroscopy and found that human eIF5-CTD is able to bind to yeast eIF1, whereas the Quad mutation in human eIF5-CTD abolishes binding to yeast eIF1 (Figures S6A and S6B, middle and right panels). Importantly, the mapped contact surface on human eIF1 overlaps the previously mapped binding surface on yeast eIF1 for yeast eIF5-CTD (Figures S6C and S6D) (Reibarkh et al., 2008), involving three conserved human eIF1 residues: F13, A14, and G101 (corresponding to yeast F12, A13, and G97) (Figure S6C versus S6D). Figure S6E shows the sequences of human and yeast eIF1 with residues experiencing CSP upon interacting with human and yeast eIF5-CTD, respectively. Interestingly, the yeast sui1-93–97 mutant exhibits a Sui2 phenotype with a well-defined mechanism, involving accelerated eIF1 release from PICs (Cheung et al., 2007).

The Quad Mutation Impairs eIF5’s Ability to Recruit eIF2-TC to PICs In Vitro

Previously, we identified eIF5’s antagonistic interplay with eIF1 and eIF2-TC within PICs (Nanda et al., 2009). The binding of eIF1 and eIF1A to the 40S subunit promotes its open conformation, favorable for direct tRNA^Met and mRNA binding to the decoding site (Passmore et al., 2007). In the presence of WT eIF1A, the yeast eIF1-G107K mutant protein diminished stable eIF2-TC loading on 40S subunits in vitro (without destabilizing mutant eIF1-G107K binding to the 40S) (Nanda et al., 2009). In this experimental situation (without mRNA), eIF2-TC loading on the 40S is contingent upon a shift to the closed conformation of the PIC, stabilizing tRNA^Met bound to the P-site. eIF1 antagonizes this shift, and the eIF1-G107K mutant exhibits a stronger antagonistic ability due to its tighter binding to the 40S ribosomal subunit. Interestingly, this effect was overcome by the addition of yeast eIF5 (Nanda et al., 2009). Thus, eIF5 enhances eIF2-TC loading by promoting eIF1 release, which is consistent with our identification of conserved overlapping surfaces for eIF2α and eIF1 in eIF5-CTD, along with our data establishing that human eIF5-CTD does not bind simultaneously to eIF1 and eIF2α in solution.

In this in vitro yeast system, we interpret the ability of the WT yeast eIF5 to enhance eIF2-TC binding to the PIC as a measure of its ability to promote eIF1 release. The Quad mutation introduced into the corresponding homologous eIF1/eIF2α-binding surface of yeast eIF5 reduces this eIF5-dependent rescue of eIF2-TC loading in reactions containing eIF1-G107K (Figure 4A). The yeast eIF5-Quad mutant exhibits significantly reduced ability to promote stable eIF2-TC recruitment relative to the WT factor, as evidenced by a 5-fold increase in the concentration of eIF5-Quad mutant required to achieve half-maximal eIF2-TC binding (Figure 4A, black curve, eIF5-Quad K_D = 0.55 ± 0.1 μM as compared to the red curve, eIF5-WT K_D = 0.10 ± 0.05 μM). Thus, the diminished ability of eIF5-Quad to enhance observable eIF2-TC loading in vitro is likely due to its impaired ability to promote the release of the eIF1-G107K mutant, which is bound tighter than eIF1-WT to 40S ribosomes.

The eIF5-Quad Mutant Destabilizes the Closed State of the PIC In Vitro

We proceeded to examine whether the Quad residues of eIF5 regulate the conformational change in the PIC response to AUG selection. Previous studies indicated that eIF1A dissociates more slowly from the PIC at AUG versus non-AUG codon (e.g., UUG) (Fekete et al., 2007; Maag et al., 2006). The in vitro eIF1A dissociation assay serves as a proxy for monitoring the opening/closing of the PIC upon start codon recognition. Stabilization of eIF1A binding upon start codon recognition is thought to indicate a closed state of the PIC, characterized by a reduced rate of eIF1A dissociation from the PIC in vitro, although the physiologically relevant dissociation of eIF1A takes place at the end of the initiation cycle, after subunit joining (Acker et al., 2006). 43S-40S mRNAs(AUG) or 43S-40S mRNA(UUG) complexes were assembled with eIF1A that was labeled at its C terminus with fluorescein, in the presence of either eIF5-WT or eIF5-Quad mutant. These labeled complexes were then chased with excess unlabeled eIF1A, and dissociation of eIF1A (fluorescently labeled) was measured over time as a decrease in fluorescence anisotropy. Using eIF5-WT, eIF1A dissociates with biphasic kinetics, with rate constants for the fast and slow phases designated k_1 and k_2, respectively (Fekete et al., 2007; Maag et al., 2006). Previous studies indicated that the slow phase corresponds to eIF1A dissociation from PICs in the closed state, whereas the fast phase represents dissociation from complexes in the open state. K_{amp} is the ratio of the amplitudes of the slow to fast kinetic phases (an apparent equilibrium constant between the two states); hence, values of K_{amp} >1 indicate that the closed complex predominates in this system.

It was shown previously that the enhancement of eIF1A binding to PICs upon start codon recognition does not happen in the absence of eIF5 (Maag et al., 2006). Consistent with previous studies by Fekete et al. (2007) and Maag et al. (2006), the kinetics of eIF1A dissociation from AUG complexes in the presence of eIF5-WT is dominated by the slow phase (K_{amp} = 6.1 ± 1.5; Table 1, AUG, row 5) (Figure 4B, red line), whereas replacing AUG with UUG in the model mRNA reduces K_{amp} several fold (to 2.5 ± 0.5), indicating a stabilization of the open state relative to the closed state (Figure 4B, black line). This indicates that eIF5 promotes the shift to the closed state preferentially in response to AUG versus UUG. Dissociation of eIF1A from AUG complexes containing the eIF5-Quad mutant showed a 4-fold reduction in K_{amp} (Table 1, AUG, K_{amp} = 1.5 ± 0.5), such that
Figure 4. Biochemical Evidence that eIF5-CTD Functions to Promote eIF1 Release and the Closed Complex

These experiments used purified yeast eIFs and ribosomes, as summarized schematically on the right.

(A) eIF5-Quad mutant reduces eIF2-TC recruitment to 43S complex (−AUG) in vitro. eIF5-Quad mutant is unable to efficiently suppress the eIF2-TC recruitment defect conferred by the G107K eIF1 mutant (corresponds to human eIF1-G112) to the same extent obtained by WT eIF5. In this experiment using yeast eIF1-G107K mutant and WT eIF1A, eIF2-TC binding to 40S is severely compromised, but this effect is rescued by adding high amounts of WT eIF5 (red curve). A yeast eIF5-Quad mutant (V316D, T317D, S357K, E358K) is not able to rescue the eIF2-TC recruitment defect imposed by eIF1-G107K (black curve). In the case of WT eIF1, eIF5 is not needed for efficient eIF2-TC recruitment under these experimental conditions (data not shown).

(B) Effect of the eIF5-Quad mutant on eIF1A dissociation from 43S (AUG)/(UUG) complexes. The eIF5-Quad mutant destabilizes 43S (AUG)/(UUG) complexes, which leads to eIF1A dissociation from PICs. The kinetic constants of eIF1A dissociation from 43S AUG or UUG complexes from Figure 3B are shown in Table 1.

(C) Effect of the eIF5-Quad mutant on GTP hydrolysis from 43S AUG complexes. The eIF5-Quad mutant has no significant effect on GTP hydrolysis (black squares) because the eIF5-Quad exhibits similar levels of hydrolysis when compared to WT eIF5 (red circles).

See also Figure S6.
5-fluoro-orotic acid (5FOA) to select against URA3 (tif5 shuffling). The plasmid encoding FLAG-tagged human eIF5 a single-copy epitope and placed under the native yeast the cloned coding sequences for either human eIF5-WT FLAG tagged (Figure 5A, rows 1–3). By contrast the constructs single-copy plasmid, and confirmed equal expression of eIF5-LEU2 encoding the KK or Quad variants of FLAG-tagged helf5 did not complement tif5-Δ (Figure 5A, rows 4 and 5). Thus, the KK or Quad substitutions, but not the DD substitutions, abolish the ability of human eIF5 to provide the essential function of eIF5 in yeast cells. Because the Quad mutation is required to disrupt binding of human eIF5-CTD to eIF1 (Figures S1B, S1D, S3A, and S3B), whereas both the KK and Quad mutations abolish eIF5-CTD binding to eIF2β-NTD; hence, we conclude that the essential partner of human eIF5-CTD in yeast cells is likely to be eIF2β-NTD.

The KK and Quad Mutations in Yeast eIF5-CTD Reduce Aberrant Initiation from a UUG Start Codon In Vivo

We proceeded to evaluate the effects of introducing the DD, KK, or Quad mutations into yeast TIF5 gene on the accuracy of start codon selection in vivo. To this end, we constructed these TIF5 mutants in the tif5-Δ strain harboring the his4-306 allele of the HIS4 gene in which the AUG start codon is altered, and translation begins on a downstream UUG codon. The strain containing WT TIF5-FL cannot grow on medium devoid of histidine (Figure 5B, row 1, –His medium) because the start codon mutation in his4-306 abolishes expression of this histidine biosynthetic enzyme. A strain containing TIF5-G58S altering the eIF5-NTD can grow on –His medium (His+ phenotype) because an in-frame UUG triplet at the third codon of his4-306 can be used as the initiation codon in cells harboring this eIF5 Sui+ mutation (Singh et al., 2005) (Figure 5B, row 2). The strain harboring TIF5-Quad did not display a slow-growth (Sig+) phenotype on +His medium (Figure 5B, row 3, +His), or a His+/Sui+ phenotype on –His medium (Figure 5B, row 3, –His). The absence of a Sui+ phenotype (Sui+) for the TIF5-Quad mutant is consistent with our in vitro analysis of eIF1A dissociation kinetics, which revealed a predominantly open state of 43S.UUG complexes harboring the yeast eIF5-Quad mutant (Figure 4B; Table 1).

As noted above, the analysis of eIF1A dissociation kinetics led us to predict that the TIF5-Quad mutant would display an Ssu− phenotype, suppressing the relaxed stringency of start codon recognition conferred by a Sui− mutation. To test this prediction, we asked whether the TIF5-Quad mutation can suppress the dominant His+/Sui− phenotype conferred by the SU13-2 mutation in eIF2β (S264Y substitution), which appears to result from elevated eIF5-independent GTPase activity by the eIF2-TC and a weakened interaction between Met-tRNA_{Met} and eIF2-GTP (Huang et al., 1997). As expected, introducing plasmid-borne SU13-2, but not WT SU13, into the his4-306 strain harboring WT TIF5 confers growth on –His medium (Figure 5C, rows 1 and 2, –His). Furthermore, the dominant His+/Sui− phenotype of SU13-2 is partially suppressed in the strain harboring a known Ssu− allele of TIF5, tif5-Δ, tif5-G62S (Asano et al., 2001), because only weak growth occurred on –His medium even after 5 days of incubation (Figure 5C, compare row 9 to row 1, –His). In agreement with our prediction, the TIF5-Quad allele confers an Ssu− phenotype nearly as strong as that of tif5-G62S (Figure 5C, compare rows 1, 7, and 9, –His). Importantly, the tif5-KK allele also confers a marked Ssu− phenotype, only slightly less than that of tif5-Quad, whereas the tif5-DD allele displays little or no Ssu− phenotype (Figure 5C, rows 3, 5, and 7, –His). The fact that the TIF5-KK mutation confers an obvious Ssu− phenotype.

### Table 1. Kinetic Constants of eIF1A Dissociation from 43S AUG/UUG Complexes

</tbody>
</table>

The rapid phase is increased in this reaction (Figure 4B, dark-blue line). For the corresponding UUG complexes, $K_{amp}$ remains low, and $k_1$ and $k_2$ both are strongly increased by the Quad substitution (Table 1, Quad mutant; UUG $K_{amp} = 1.2 \pm 0.2$) (Figure 4B, light-blue line), indicating that the Quad mutation should not confer the ability to initiate from the UUG codon. The Quad mutant’s role as a GAP remains intact as evidenced by the ability to induce GTP hydrolysis similar to eIF5-WT (Figure 4C). Therefore, we conclude that the eIF5-Quad mutant destabilizes the closed state of the PIC relative to the open state, without affecting the GAP function. These findings led us to predict that the eIF5-Quad mutation will reduce the ability to access the closed conformation inappropriately at UUG codons in Sui− mutants, thereby conferring an Ssu− phenotype in yeast. This turns out to be the case, as described below.

**eIF2β:eIF5-CTD Interaction Is Critical for Human eIF5 to Complement Yeast eIF5 Deletion In Vivo**

We turned our attention to the in vivo function of the eIF5-CTD interaction network and assessed whether the mutations in the CTD exhibit a phenotype consistent with our biochemical and biophysical data. We employed an in vivo assay that exploits the ability of human eIF5 to provide the essential function of eIF5 in a yeast strain deleted for the chromosomal gene encoding eIF5 (tif5-Δ) (Maiti and Maitra, 1997). Here, we introduced into yeast the cloned coding sequences for either human eIF5-WT or the -DD, -KK, or -Quad mutants, tagged with the FLAG epitope and placed under the native TIF5 promoter on a LEU2 single-copy plasmid, and confirmed equal expression of eIF5-CTD and mutant forms by western analysis (Figure 5A, bottom two gels). The plasmids were then tested for the ability to replace a single-copy URA3 TIF5 plasmid in a tif5-Δ strain using the drug 5-fluoro-orotic acid (5FOA) to select against URA3 (plasmid shuffling). The plasmid encoding FLAG-tagged human eIF5 harboring the DD substitutions (helf5-DD-FLAG) complemented tif5-Δ similar to those encoding human eIF5-WT untagged or FLAG tagged (Figure 5A, rows 1–3). By contrast the constructs encoding the KK or Quad variants of FLAG-tagged helf5 did not complement tif5-Δ (Figure 5A, rows 4 and 5). Thus, the KK or Quad substitutions, but not the DD substitutions, abolish the ability of human eIF5 to provide the essential function of eIF5 in yeast cells. Because the Quad mutation is required to disrupt binding of human eIF5-CTD to eIF1 (Figures S1B, S1D, S3A, and S3B), whereas both the KK and Quad mutations abolish eIF5-CTD binding to eIF2β-NTD; hence, we conclude that the essential partner of human eIF5-CTD in yeast cells is likely to be eIF2β-NTD.

The KK and Quad Mutations in Yeast eIF5-CTD Reduce Aberrant Initiation from a UUG Start Codon In Vivo

We proceeded to evaluate the effects of introducing the DD, KK, or Quad mutations into yeast TIF5 gene on the accuracy of start codon selection in vivo. To this end, we constructed these TIF5 mutants in the tif5-Δ strain harboring the his4-306 allele of the HIS4 gene in which the AUG start codon is altered, and translation begins on a downstream UUG codon. The strain containing WT TIF5-FL cannot grow on medium devoid of histidine (Figure 5B, row 1, –His medium) because the start codon mutation in his4-306 abolishes expression of this histidine biosynthetic enzyme. A strain containing TIF5-G58S altering the eIF5-NTD can grow on –His medium (His+ phenotype) because an in-frame UUG triplet at the third codon of his4-306 can be used as the initiation codon in cells harboring this eIF5 Sui+ mutation (Singh et al., 2005) (Figure 5B, row 2). The strain harboring TIF5-Quad did not display a slow-growth (Sig+) phenotype on +His medium (Figure 5B, row 3, +His), or a His+/Sui+ phenotype on –His medium (Figure 5B, row 3, –His). The absence of a Sui+ phenotype (Sui+) for the TIF5-Quad mutant is consistent with our in vitro analysis of eIF1A dissociation kinetics, which revealed a predominantly open state of 43S.UUG complexes harboring the yeast eIF5-Quad mutant (Figure 4B; Table 1).

As noted above, the analysis of eIF1A dissociation kinetics led us to predict that the TIF5-Quad mutant would display an Ssu− phenotype, suppressing the relaxed stringency of start codon recognition conferred by a Sui− mutation. To test this prediction, we asked whether the TIF5-Quad mutation can suppress the dominant His+/Sui− phenotype conferred by the SU13-2 mutation in eIF2β (S264Y substitution), which appears to result from elevated eIF5-independent GTPase activity by the eIF2-TC and a weakened interaction between Met-tRNA_{Met} and eIF2-GTP (Huang et al., 1997). As expected, introducing plasmid-borne SU13-2, but not WT SU13, into the his4-306 strain harboring WT TIF5 confers growth on –His medium (Figure 5C, rows 1 and 2, –His). Furthermore, the dominant His+/Sui− phenotype of SU13-2 is partially suppressed in the strain harboring a known Ssu− allele of TIF5, tif5-Δ, tif5-G62S (Asano et al., 2001), because only weak growth occurred on –His medium even after 5 days of incubation (Figure 5C, compare row 9 to row 1, –His). In agreement with our prediction, the TIF5-Quad allele confers an Ssu− phenotype nearly as strong as that of tif5-G62S (Figure 5C, compare rows 1, 7, and 9, –His). Importantly, the tif5-KK allele also confers a marked Ssu− phenotype, only slightly less than that of tif5-Quad, whereas the tif5-DD allele displays little or no Ssu− phenotype (Figure 5C, rows 3, 5, and 7; –His). The fact that the TIF5-KK mutation confers an obvious Ssu− phenotype...
suggests that the weakened binding of eIF5-CTD to eIF2β produced by the KK substitution is responsible for this phenotype. These findings provide strong support for the conclusion that disrupting the interaction of eIF5-CTD with eIF2β destabilizes the closed conformation of the PIC, increasing the stringency of start codon recognition and thus decreasing initiation at near-cognate UUG codons in vivo.

In Vivo Evidence that the KK and Quad Substitutions in eIF5-CTD Confer Sui− Phenotypes by Decreasing eIF1 Release from the PIC

Our biochemical analysis of the eIF5-Quad mutant showed a reduction in eIF2-TC recruitment to PICs, which is indicative of a defect in promoting eIF1 dissociation upon AUG recognition. The previously described G107R and G107K eIF1 mutants exhibit the same defect in eIF2-TC recruitment. The G107R/K substitutions increase the UUG:AUG ratio (Sui− phenotype) primarily by decreasing initiation at AUG rather than elevating UUG initiation (Nanda et al., 2009). By contrast, other eIF1 mutations, notably the 93–97 substitution in helix α2 (Cheung et al., 2007), appear to increase the UUG:AUG ratio by provoking more rapid dissociation at UUG codons owing to weaker eIF1 binding to the PIC. Accelerated eIF1 release likely also explains the Sui− phenotype of sui1-K60E (Martin-Marcos et al., 2011) because Lys-60 contacts 18S rRNA in the eIF1:40S crystal structure (Rabl et al., 2011), and overexpression of sui1-K60E suppresses its Sui− phenotype in the manner observed previously for sui1-93–97 (data not shown). Because the Quad substitution impairs eIF1 dissociation, we reasoned that it should not suppress the elevated UUG:AUG ratio conferred by the G107R/K substitutions because they also impede eIF1 dissociation but that it should suppress the Sui− phenotypes of the 93–97 and K60E substitutions by mitigating the accelerated eIF1 dissociation they engender.

We tested these predictions by examining a set of sui1Δ his4-301 yeast strains (with a different start codon mutation at
HIS4) containing plasmid-borne TIF5 and SUI1 alleles encoding the elf5 and elf1 mutants of interest and the chromosomal TIF5 allele placed under the GAL1 promoter to enable its repression on glucose medium. As expected, the WT TIF5 strain expressing elf1-93–97 has a Slg⁻ phenotype at 37°C on +His (glucose) medium but can grow on media containing no histidine, indicating the Sui⁻ phenotype (Cheung et al., 2007). Interestingly, the TIF5-KK and TIF5-Quad alleles improve the growth of sui1-93–97 cells on +His medium but diminish their growth on −His medium, whereas the TIF5-DD allele only reduces growth on −His (Figure 6A). These results suggest that the KK and Quad mutations suppress the Sui⁻ phenotype of sui1-93–97 cells more effectively than does TIF5-DD. Supporting this, the KK and Quad mutations exceed DD in decreasing the UUG:AUG initiation ratio in sui1-93–97 cells measured using HIS4-lacZ fusions with an AUG or UUG start codon. Thus, the KK and Quad mutations reduce the UUG:AUG ratio by ≈40%, similar in magnitude to reductions observed for Ssu⁻ substitutions in elf1A (Saini et al., 2010), whereas the DD mutation produces only a ≈20% reduction in the ratio. Importantly, the KK and Quad mutations also exceed the DD mutation in reducing the His⁻/Sui⁻ phenotype and elevated UUG:AUG ratio in sui1-K60E cells (Figures S7A and S7B).

The G107R substitution in elf1 increases the UUG:AUG ratio to the same extent as does the 93–97 substitution (compare Figures 6B and 6D). Importantly, however, none of the CTD mutations of elf5 produces a significant reduction in this ratio (Figure 6D). In addition the KK and Quad mutations exacerbate the Slg⁻ phenotype of sui1-G107R cells (Figure 6C), opposite the effect displayed in sui1-93–97 cells, and similar findings were observed for the mechanistically
related G107K mutation (Figures S7C and S7D). These findings support our prediction that the KK and Quad substitutions would not suppress the elevated UUG: AUG initiation ratio and would intensify the defect in elf1 release on AUG recognition, conferred by elf1-G107R/K. These results provide in vivo evidence that the KK and Quad substitutions impair the elf5-CTD function in releasing elf1 from the complex upon start codon recognition. Our molecular interpretations of the Ssu− and Slg+ phenotypes of the various mutants harboring the elf5-CTD mutations are shown in Tables S2 and S3, respectively.

**DISCUSSION**

eIF1 binds in the vicinity of the P-site on the 40S subunit and contacts Met-tRNA<sub>Met</sub> (Lomakin et al., 2003; Rabl et al., 2011). Therefore, we sought to use the elf1:elf5-CTD model to infer the position of elf5-CTD in the PIC, by superimposing the elf1:elf5-CTD complex onto the elf1:40S structure (Rabl et al., 2011) by aligning the common component: elf1 (Figures 7A and 7B). The resulting model places elf5-CTD in the vicinity of the Met-tRNA<sub>Met</sub>, consistent with the elf5-NTD binding to elf2<sub>y</sub> near the 3′ end of the tRNA (Alone and Dever, 2006; Conte et al., 2006).

The conclusion that the CTD of elf5 promotes elf1 dissociation is supported by our findings that the Quad substitution impairs the ability of elf5, when added in excess, to reverse the antagonistic effect of elf1-G107K on elf2-TC binding in the reconstituted system. The mechanism wherein overlapping surfaces on the CTD of elf5 are utilized to promote elf1 dissociation was not known. We provide biochemical evidence that the CTD of elf5 plays a previously unknown role in the promotion of elf1 dissociation upon AUG recognition via its dynamic interaction with elf1 and elf2<sub>β</sub>, which is based on the following two findings: (1) the Quad substitution impairs elf5’s ability to promote stable recruitment of elf2-TC to PICs containing elf1-G107K (which binds with greater affinity to 40S ribosomes) without mRNA in vitro; and (2) the Quad substitution destabilizes closed PIC conformation with mRNAs upon start codon recognition. It is important to note that the role of elf5-CTD in promoting elf1 release is independent of the elf5 GAP function catalyzed by the NTD.

A key question is whether the newly identified function of the CTD of elf5 in promoting elf1 release involves both of its interactions with elf1 and elf2<sub>β</sub>. We show here that the KK substitution on the CTD of elf5 is sufficient to drastically reduce its binding to elf2<sub>β</sub>, but not to elf1. Thus, it can be deduced that disrupting the interaction of elf5-CTD with elf2<sub>β</sub> is likely to be responsible for destabilizing the closed PIC conformation and conferring the Ssu− phenotypes displayed by the elf5-KK and elf5-Quad mutations. In fact it was shown previously that elimination of K boxes 1 and 2 from elf2<sub>β</sub> also confers an Ssu− phenotype (Laurino et al., 1999). Hence, it seems likely that the Ssu− phenotypes produced by these newly identified substitutions in the CTD of elf5 (along with the previously identified elf2<sub>β</sub>-NTD Ssu− phenotype) directly impact the linkage of elf2<sub>β</sub> with elf5 within the PIC.

It is plausible that the elf1:elf5-CTD complex is stabilized by the mutual interaction of these factors with elf3c, which was demonstrated in vitro for the cognate yeast proteins (Asano et al., 2000). We propose that the elf1:elf5-CTD interaction is redundant with other interactions that stabilize elf1 binding to the 40S leading to an open PIC conformation; hence, eliminating this interaction is probably not sufficient to accelerate elf1 dissociation at UUG codons in vivo. Our conclusion that elf5-CTD stabilizes the closed conformation of PICs upon start codon recognition via its interaction with elf1 and elf2<sub>β</sub> was based on the cumulative breadth of data ranging from NMR spectroscopy, ITC, SAXS, and in vitro yeast-reconstituted system. The in vitro assays employed in this study, which include elf1, elf1A, elf2-TC, elf5, and 40S ribosomes (with and without mRNA), utilize the basic components for start codon recognition and have been consistently implemented as useful tools to decipher biochemical events surrounding start codon recognition (Maag et al., 2006; Nanda et al., 2009). Based on our in vitro assays, we propose that elf5 interactions, particularly with its CTD, are sufficient to promote elf1 release by stabilizing the closed complex via its interaction with elf2<sub>β</sub>. Our hypothesis was further examined using in vivo experiments, wherein we dissect the cause of Ssu− phenotypes produced by mutations in the CTD of elf5. We show that the KK and Quad mutants exhibit strong Ssu− phenotypes, which further substantiates the role of elf5-CTD in facilitating the stabilization of the closed state of PICs upon start codon recognition via its dynamic interplay with elf1 and elf2<sub>β</sub).

The common interface on elf5-CTD that contacts elf2<sub>β</sub> also interacts with elf1, in a manner disrupted by the Quad substitution. elf1 and elf2<sub>β</sub> do not form a higher-order complex with elf5-CTD in our SAXS reconstitution assay; hence, an intriguing model would be that elf5-CTD first interacts with elf1 in the open, scanning conformation of the PIC and then switches partners to interact with elf2<sub>β</sub> in the closed conformation upon AUG recognition (Figure 7C). In this view the interaction network (including elf5-CTD) positions elf1 in the decoding site and mediates scanning. We propose the following possible model of events surrounding start codon recognition. elf5-CTD binds to elf2<sub>β</sub>, which in turn favors the release of elf1 from the PIC and essentially puts an end to the ribosomal scanning mechanism. This would also impede elf1’s reassociation with the 40S and drive the conformational rearrangement of the PIC to the closed state.

The hypothesis that the disruption of the elf1:elf5-CTD interaction by elf2<sub>β</sub> triggers the critical shift from the open state (scanning competent) to the closed state (scanning incompetent) led us to conclude that the CTD of elf5 stabilizes the closed state of the PIC in which elf1 is no longer bound (Figure 7C). This model is fully consistent with our biophysical, biochemical, and genetic data wherein we strategically disrupt the elf5-CTD:elf2<sub>β</sub> interaction that destabilizes the closed state of the complex and prevents elf5-CTD from promoting elf1 release. We do note that in vivo other initiation factors, e.g., possibly elf1A, elf3, or elf4G, could also play contributing roles in the observed Ssu− phenotype caused by mutations in the CTD of elf5. This study opens an avenue for further investigation to continue deciphering the effect of elf5-CTD’s interaction with its cognate partners and its crucial role in mediating the closure of PICs upon start codon recognition.
Figure 7. Modeling the eIF1:eIF5-CTD Complex in the Context of the eIF1:40S Structure and Schematic Showing the role of eIF5-CTD in Promoting Start Codon Recognition

(A) The eIF1:eIF5-CTD complex derived from the HADDOCK software was superimposed on the position of human eIF1 on the small ribosomal subunit (Lomakin et al., 2003; Rabl et al., 2011), shown as a magenta ribbon. The modeled position of the human eIF5-CTD (yellow) was obtained by aligning eIF1 from the eIF1:eIF5-CTD complex (Figure 1G) to ribosome-bound eIF1, eIF1A (green), mRNA (blue), and P-site tRNA (orange) are also shown for reference. The P-site tRNA is shown in a P/P orientation. Note that the actual orientation of the MettRNAi on the 40S subunit cannot be exactly in a P/P orientation because it would clash with eIF1 (Rabl et al., 2011) and is likely to change over the course of translation initiation. In the right panel the modeled eIF1A:eIF1/eIF5-CTD:40S ribosomal complex was rotated 90° along the y axis and magnified.

(B) In the left panel the eIF1A:eIF1/eIF5-CTD:40S ribosomal complex is in the same orientation as the left panel of (A) but magnified. In the right panel the modeled eIF1A:eIF1/eIF5-CTD:40S ribosomal complex was rotated 90° along the x axis from the left panel.

(C) Schematic diagram of eIF5-CTD gating the release of eIF1 after start codon selection, followed by subsequent stabilization of the PIC by eIF5. (i.) The open 43S conformation allows for mRNA recruitment and relatively unstable eIF2-TC binding. During the assembly stage of the PIC, eIF5-CTD (HEAT) interacts with eIF1. (ii.) The 43S PIC scans the mRNA in an open conformation until start codon recognition. During this scanning stage the eIF5-NTD induces eIF2β to cleave GTP. Start codon recognition sets the stage for large conformational rearrangements on the subunit interface ensuring the closed state of the PIC. eIF2β exhibits a stronger affinity for the overlapping binding surface of the eIF5-CTD than eIF1; hence, the disruption of the eIF1:eIF5-CTD interaction by eIF2β allows for an indirect mechanism to dislodge eIF1 from the 43S PIC. Upon release of eIF1 the free phosphate is subsequently released. (iii.) eIF5-CTD stabilizes the closed ribosomal conformation of PICs upon start codon selection.
EXPERIMENTAL PROCEDURES

Biophysical Experiments and Analyses

NMR experiments were performed as described previously by Marintchev et al. (2007) and are written in more detail in the Extended Experimental Procedures. We recorded a set of triple resonance experiments needed for backbone assignments of human eIF5-CTD. Assignments were completed for 95% of the residues in the human eIF5-CTD, using standard techniques and IBIS (Hyberts and Wagner, 2003). Chemical shift mapping was done as previously described by Marintchev et al. (2007). A paramagnetic spin-label strategy was used to obtain intermolecular distance restraints between human eIF1 and eIF5-CTD (Battiste and Wagner, 2000).

SAXS and ITC experiments are also described in more detail in the Extended Experimental Procedures. SAXS of eIF5, eIF1:eIF5-CTD, and eIF1:eIF5-CTD+eIF2(-NTD) was measured in 20 mM Tris-HCl (pH 7.4), 200 mM NaCl, 0.5 mM TCEP, and eIF5-CTD at a final concentration of 90 μM, whereas eIF1 concentrations were in the range from 90 to 1,800 μM. Protein samples for ITC experiments were prepared in 20 mM Tris-HCl (pH 7.2), 200 mM NaCl, 0.5 mM TCEP, and 0.5 mM EDTA. A MicroCal iTC200 calorimeter was run at an equilibrium temperature of 25 °C. The concentration of the protein in the well was roughly ten times the estimated Kd, and the concentration of the protein in the syringe was seven times the one in the well.

Yeast Biochemistry and Genetics Experiments

Yeast biochemistry experiments were performed as described previously by Maag et al. (2006) and Nanda et al. (2009). eIF2-TC recruitment to 43S PICs was plotted as a function of time (Maag et al., 2006). GTP hydrolysis experiments at an equilibrium temperature of 25 °C were performed as described previously by Algire et al. (2005). Yeast genetics experiments were performed as described previously by Battiste and Wagner (2000), Marintchev et al. (2007) and are written in more detail in the Extended Experimental Procedures.

SUPPLEMENTAL INFORMATION

Supplemental Information includes seven figures, five tables, Extended Experimental Procedures, Extended Results, and an Extended Discussion and can be found with this article online at doi:10.1016/j.celrep.2012.04.007.
