A one-dimensional magnonic crystal for forward volume spin waves (FV SWs) is demonstrated using eight pairs of Cu stripes fabricated on a 1-mm wide \times 14-mm long \times 10.2- μ m thick yttrium iron garnet (YIG) waveguide and a SW absorber of 30-nm-thick Au film. The development of this crystal is challenging due to strong spectral oscillations caused by edge reflections and process difficulties associated with YIG magnonic crystals. A magnonic band gap with a depth of -4.6 dB is observed at a frequency of 1.80 GHz for a FV SW excited by a 50- μ m-wide microstrip line, which is in good agreement with simulation results using three-dimensional modeling in the radio frequency region. The obtained performance is illustrated by plotting the depth of the respective band gaps vs the pair number of the stripes. This value is compared with that obtained in previous studies.

I. INTRODUCTION

One dimensional (1D) magnonic crystals (MCs) for controlling the propagation of spin waves (SWs) have been widely studied and reviewed [1–13], primarily because of the unique properties of such crystals, e.g., the guiding and filtering of SWs [14–17], confinement of SWs [18–21], and slowing (phase shifting) of SWs. MCs are based on phase interference of SWs, and many applications have been proposed or are in development based on the advantages of MCs for controlling SWs. In particular, MCs can be used in SW integrated circuits (ICs), including logic gates [22–28]. SW ICs have attracted attention as next-generation computing elements that generate only a few Joules of heat during propagation. For these applications, forward volume SWs (FV SWs) are the most suitable mode because of their in-plane isotropy. FV SWs propagate in out-of-plane magnetized media without changing their wavelength, even in curved, oblique, or rectangular waveguides [22,24]. Hence, the use of phase interference

including MCs with FV SWs is significantly promising. However, only a few experimental studies [29] have researched MCs using FV SWs, although many experimental reports have described two modes—specifically, surface SWs (S SWs) [30–35] and backward volume SWs (BV SWs) [3,29,36–38]. This is mainly because of the significant noise in the FV SW configuration, which makes it difficult to observe a magnonic band gap (MBG) in experiments that employ low damping materials (yttrium iron garnets, YIG) as waveguides. In this study, we demonstrate a 1D MC for FV SW propagation in YIG film by introducing a noise suppression technique based on metalization [22,39,40]. The radio frequency (rf) powers used for exciting SWs in this study are in the linear region, and the SWs are dipolar SWs because the wavenumber is in the order of mm [8]. The observed MBG is analyzed using an rf simulation and compared with previous reports on MCs.

II. SIMULATION AND DISCUSSION

A. YIG waveguide

First, we calculate the single-mode propagation of FV SWs without periodic structure. A 10.2- μ m-thick 14-mm-long YIG line is used as a SW waveguide in a three-dimensional (3D) simulator (CST Microwave Studio 2016 SP7) based on the finite integration technique (FIT) [41,42]. The parameters used in the simulation are the saturation magnetization $4\pi M_s = 1749$ G, relative permittivity

$\epsilon_r = 15.3$, gyromagnetic ratio $\gamma = 2.8$ MHz/Oe, and magnetic damping $\alpha = 7.4 \times 10^{-4}$. The internal magnetic field $H_{\text{in}} = 622$ Oe is perpendicularly (z direction) applied to the YIG waveguide. This YIG is placed onto two microstrip lines (MSLs). Cu with a thickness of $18 \mu\text{m}$, width of $50 \mu\text{m}$, and conductivity σ of 5.96×10^7 S/m is used to fabricate the MSL. The MSL is placed onto a dielectric substrate ($\epsilon_r = 4.4$) with a thickness $t_d = 0.5$ mm, and the backside of the dielectric substrate is covered by Cu and set as ground level. These parameters are the same as those used in our prior simulation [40].

To ensure single-mode propagation of the FV SW and to maximize the input amplitude of the SW, the dispersion curve of the SW in the YIG waveguide is calculated before modeling using magnetostatic equations [8]. The wavevector in the width (y) direction k_m of the SW in the waveguide is quantized as

$$k_m = \frac{m\pi}{w} \quad (m = 0, 1, 2, 3, \dots), \quad (1)$$

where w is the width of YIG, and the x -directional wavevector k is expressed with the thickness (z) direction wavenumber k_z as [43]

$$k = \sqrt{k_z^2 - k_m^2}. \quad (2)$$

Using the boundary conditions [8], the dispersion curve is derived as follows:

$$k = \sqrt{\left[\frac{1}{2t_{\text{YIG}}\sqrt{\mu}} \ln \left(\frac{(\sqrt{\mu} - \tanh(k_z t_d))(\sqrt{\mu} - 1)}{(\sqrt{\mu} + \tanh(k_z t_d))(\sqrt{\mu} + 1)} \right) \right]^2 - \left(\frac{m\pi}{w} \right)^2} \quad (m = 0, 1, 2, 3, \dots), \quad (3)$$

where t_{YIG} is the thickness of YIG ($= 10.2 \mu\text{m}$). μ is the diagonal component of the permeability of YIG and

is expressed as:

$$\mu = 1 + \frac{(\gamma H_{\text{in}} + i\alpha f)(\gamma \cdot 4\pi M_s)}{(\gamma H_{\text{in}} + i\alpha f)^2 - f^2}, \quad (4)$$

where f is frequency [8]. In Eq. (3), $k_z t_d$ is sufficiently large, hence $\tanh(k_z t_d) \approx 1$. Therefore, Eq. (3) can be converted to

$$k = \sqrt{\left(\frac{1}{t_{\text{YIG}}\sqrt{\mu}} \ln \frac{\sqrt{\mu} - 1}{\sqrt{\mu} + 1} \right)^2 - \left(\frac{m\pi}{w} \right)^2} \quad (m = 0, 1, 2, 3, \dots). \quad (5)$$

Figure 1(a) shows a plot of Eq. (5) for $m = 1$ and 2 at $f = 1.8$ GHz. When w is between approximately 0.75 and approximately 1.25 mm, a single-mode SW can be obtained. Hence, a width w of 1 mm is used in all subsequent simulations and experiments. The wavenumber k is 3.7578 mm^{-1} and the wavelength λ is 1.672 mm for $w = 1 \text{ mm}$. The dispersion curves for $w = 1 \text{ mm}$ with various m are shown in Fig. 1(b). A single mode is obtained in the frequency range between approximately 1.780 and approximately 1.815 GHz for $m = 1$. The spectral robustness is approximately 35 MHz, which is sufficiently large for the experiments.

Based on these estimations, the waveguide feature is determined and 3D simulations are conducted. Figures 1(c) and 1(d) show the calculated distribution of an absolute value of the x -directional magnetic-flux density $|b_x|$ as the amplitude of FV SW at the surface of the YIG waveguide for $w = 1$ and 2 mm, respectively. Disordered propagation is observed during multimode propagation ($w = 2 \text{ mm}$). MCs are based on phase interference; hence, such a disordered propagation hinders the exhibition of a MBG. However, in contrast, the 1-mm-wide waveguide exhibits a monotonically decaying amplitude relative to the direction of propagation. Hence, a single-mode propagation of FV SW is obtained with a 1-mm-wide YIG waveguide in simulation.

FIG. 1. (a) Calculated wavenumber as a function of the width of the YIG waveguide at a frequency of 1.8 GHz. (b) Dispersion curve of the FV SW at $w = 1$ mm. (c), (d) Calculated amplitude distribution of the FV SW in YIG waveguides with widths of $w = 1$ and 2 mm. The thickness of the YIG t_{YIG} is $10.2 \mu\text{m}$ and the saturation magnetization of $4\pi M_s$ is 1749 G. The internal magnetic field in the YIG is $H_{\text{in}} = 622$ Oe.

B. Modulation of the wavelength using Cu

We employ metallization techniques to modulate the wavelength of the FV SW for realizing MCs [18,19,30,39,44,45]. As shown in Ref. [39], the wavenumber $k_{\text{Cu-YIG}}$ of the FV SW propagation in Cu-YIG is twice that in bare k_{YIG} ($=k$). Thus, at $f = 1.8$ GHz, the calculated wavenumbers are $k_{\text{YIG}} = 3.7578 \text{ mm}^{-1}$ ($\lambda_{\text{YIG}} = 1.672 \text{ mm}$) and $k_{\text{Cu-YIG}} = 1.8789 \text{ mm}^{-1}$ ($\lambda_{\text{Cu-YIG}} = 3.344 \text{ mm}$), respectively.

C. Design of the magnonic crystal

The pitch of the Cu stripes is determined using the following values. The length of the bare YIG area L_{YIG} is $418 \mu\text{m}$ ($=\lambda_{\text{YIG}}/4$), the length of the Cu-YIG area $L_{\text{Cu-YIG}}$ is $836 \mu\text{m}$ ($=\lambda_{\text{Cu-YIG}}/4$), and the eight pairs of Cu lines are introduced onto the YIG waveguide as shown in Fig. 2. The lattice constant is 1.254 mm . The edges of the YIG waveguide outside the MSLs are covered by 30-nm-thick Au films, which function as SW absorbers for suppressing edge reflections and spectral noise [22,39,40,46]. The length of the Au $L_{\text{Au-YIG}}$ is 1.8 mm , the distance between the edges of the Au film and the edges of the MSL is 0.2 mm , the conductivity of the Au is $4.56 \times 10^7 \text{ S/m}$, and the position and thickness of the SW absorbers are as discussed and specified in Ref. [40].

The calculated transmission spectra of the FV SW with and without SW absorbers and with and without MCs are shown in Fig. 3. In Fig. 3(a), the YIG without the SW absorber does not exhibit distinct MBGs even with eight pairs of Cu strips because of the significant noise generated by the edge reflections. In contrast, the YIG with SW absorbers exhibits smooth transmission spectra, and the effect of MC, namely, distinct MBGs, is evident at $f = 1.8$ GHz. Hence, the SW absorbers are essential in order to observe MBGs in the FV SW. The estimated depth of the MBGs is about -3.3 dB .

FIG. 2. 1D MC model containing eight pairs of Cu stripes. This model is used when simulating the FV SWs. (a) Overview of the simulation model and (b) an enlargement of the region close to the MSL and SW absorbers. The length of Au-YIG, Cu-YIG, and YIG are shown as $L_{\text{Au-YIG}}$, $L_{\text{Cu-YIG}}$, and L_{YIG} , respectively.

FIG. 3. (a) Calculated transmission spectra of the FV SW propagating in the YIG waveguide without SW absorbers and (b) with SW absorbers. The blue lines represent the transmission through the bare YIG waveguide, while the red lines indicate transmission through the YIG with the MC.

III. EXPERIMENT AND DISCUSSION

A. Sample preparation

An MC similar to the one simulated in the last section is lithographically prepared as shown in Fig. 4. A $10.2\text{-}\mu\text{m}$ -thick YIG grown on a gadolinium gallium garnet (GGG) substrate is cut into 1-mm-wide and 14-mm-long sections using a dicing saw (Disco, DAD321), as shown in Figs. 4(b) and 4(c). A 10-nm-thick layer of Ti is deposited

FIG. 4. Process for preparing the MC. (a) Overview of the fabricated sample. (b, c) The bare YIG is cut with a dicing saw. (d) Cu-Ti is deposited onto the YIG. (e) The resist is exposed by a mask aligner. (f) The Cu-Ti is etched. (g) Resist coating for SW absorbers. (h) Au-Ti deposition. (i) Lift-off step.

by rf magnetron sputtering (Shimadzu, HSR551) under 20 mTorr Ar at a flow rate of 5 sccm using a rf power of 70 W and a deposition rate of 6.7 nm/min. Next, 1- μ m-thick Cu is deposited by the same machine under 5 mTorr Ar at a flow rate of 5 sccm with a rf power of 100 W and a deposition rate of 50 nm/min [Fig. 4(d)]. After sonication using acetone and isopropanol (IPA), the sample is baked at 170 °C for 2 min. A 2- μ m-thick layer of resist AZ5214 is spin coated onto the sample followed by baking at 100 °C for 1 min. The resist on the sample is exposed using a mask aligner (Canon, PLA501F) for 16 s followed by development using the solution AZ400:H₂O = 1:5 for 200 s [Fig. 4(e)]. To etch the Cu and Ti, the sample is dipped into FeCl₃ for 5 min and H₂O₂:NH₃ = 50:1 for 5 min. The remaining resist is removed by dipping into AZ700 for 5 min followed by cleaning using acetone and IPA without sonication [Fig. 4(f)]. The SW absorbers are then fabricated onto this sample using the same resist as above. After spin coating, exposure, development, and baking [Fig. 4(g)], a 30-nm-thick Au layer is deposited by the same magnetron sputtering machine under 3 mTorr Ar at a flow rate of 5 sccm with a rf power of 40 W and a deposition rate of 16 nm/min, as shown in Fig. 4(h). After liftoff using AZ700 without sonication, the sample is cleaned with acetone and IPA [Fig. 4(i)]. The resulting sample is placed onto two MSLs-dielectric substrates [Flame Retardant Type 4 (FR4)], as shown in Fig. 4(a). The YIG surface is in contact with that of the MSLs. The sample is fixed by a ceramic sheet and nonmagnetic screws using a jig composed of brass. The two MSLs are connected to a vector network analyzer (VNA, Anritsu 37347C) via rf connectors. The bias magnetic field H_0 is perpendicularly applied to the sample using an electromagnet controlled using a proportional integral derivative (PID) method. The Gauss meter used in this setup is a F. W. Bell 7030 instrument and the current source is a Keysight N5750A. Transmission spectra are then obtained, followed by spin wave spectroscopy by varying the magnetic field.

B. Observation of the magnonic band gap

Figure 5(a) shows the obtained transmission spectra of the YIG waveguide with and without the MC. The bias magnetic field H_0 is 2.30 kOe. It can be seen that the simulated spectra shown in the previous section overlap. As per our design specifications, the MBG is generated at $f = 1.80$ GHz, which is in excellent agreement with the results of our simulation. The depth of the MBG is approximately -4.6 dB in the experiment and approximately -3.3 dB in the simulation. The difference between the experiment and simulation results may be due to the imperfectness of the sample and the modeling mesh-size limitation in the simulation. The large insertion loss is mainly due to an impedance mismatch at the 50- μ m-wide MSLs. This can be improved in the future by optimizing the design of these antennas.

Figure 5(b) shows the FV SW spectroscopy image with varying magnetic fields from 2.25 kOe to 2.35 kOe with 0.5-Oe steps. The observed kinks in the SW spectroscopy might be caused by the PID control error including the quantization error of an analog digital (AD) converter. In the red region, the FV SW is not excited. The blue area shows the propagation of the FV SW. Within this region, the right blue line corresponds to the observation and illustrates the MBG. The slope of this line is equal to the gyromagnetic ratio γ of 2.8 MHz/Oe; thus, this strongly indicates the obtained results are due to the FV SW. The many lines observed in the high-frequency region are due to higher modes generated by the MSL.

C. Comparison and discussion

The obtained depth of the MBG is compared with that of previous reports including those using the other two modes (S SW and BV SW), as shown in Fig. 6 and Table I. The color of the plots indicates the mode, and the shape of the plots indicates the type of structure used to realize the MCs. From the figure, it is evident that this study is one of

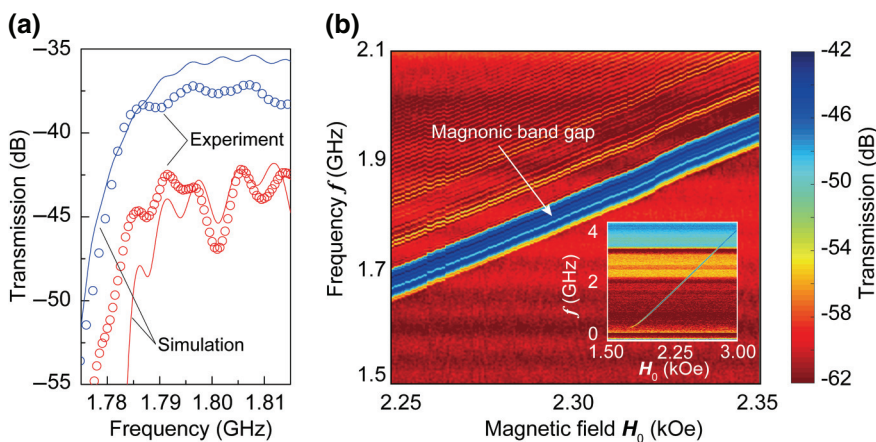

FIG. 5. (a) MBG for the FV SWs using an MC composed of Cu stripes on a YIG waveguide. The bias magnetic field H_0 is 2.30 kOe. The blue line and circles show the transmission spectra of the YIG waveguide. The red line and circles represent that of the YIG with the MC. (b) SW spectroscopy image of the MBG with a varying applied magnetic field H_0 . The inset shows the wide range of the same spectra.

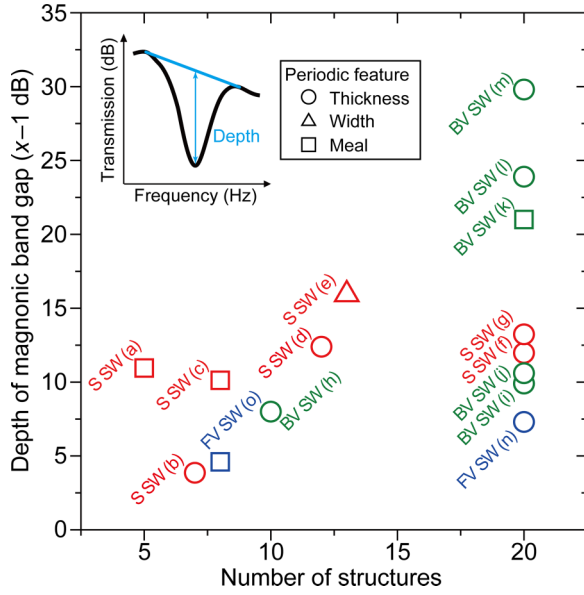

FIG. 6. Depth of the MBGs. The symbols in brackets correspond to the applicable reference shown in Table I. The red color represents the S SW, the green color represents the BV SW, while the blue color represents the FV SW. The circles indicate the MBGs using thickness modulation, the triangle indicates the MBGs using width modulation, and the squares indicate the same using metal stripes. This study is shown as (o).

a few reports on MCs for FV SW and the depth is comparable to that of the other modes. Because of the small number of Cu-stripe pairs, the depth in the experiment at -4.6 dB is not as large; however, this is similar to the results of the simulation. Hence, the increase in the number of stripes should increase the depth of the MBG.

TABLE I. Comparison of the depth of the MBGs. All data are obtained from experimental reports shown with evaluable units. The number of structures means the number of metal lines, grooves, or a pair of notches in the waveguides. The depths show that of the first-order MBGs. The first-order MBGs for S SW and FV SW are observed at the lowest frequency, and those for BV SW are observed at the highest frequency.

Symbol in Fig. 6	Reference	Mode	Periodic feature	Number of structures	Depth (dB)	f (GHz)	d (μm)	H_0 (kOe)
(a)	[44]	S SW	Metal	5	-11.0	2.4	7.7	0.37
(b)	[30]	S SW	Thickness	7	-3.9	4.8	10	1
(c)	[30]	S SW	Metal	8	-10.1	4.9	10	1
(d)	[32]	S SW	Thickness	12	-12.4	4.1	8.3	0.770
(e)	[33]	S SW	Width	13	-15.9	2.5	10	0.444
(f)	[35]	S SW	Thickness	20	-12.0	2.9	9	0.380
(g)	[34]	S SW	Thickness	20	-13.2	7.2	5.5	1.845
(h)	[36]	BV SW	Thickness	10	-8.0	7.7	5.5	2.016
(i)	[38]	BV SW	Thickness	20	-9.9	6.6	100	1.650
(j)	[29]	BV SW	Thickness	20	-10.6	4.3	100	1.075
(k)	[45]	BV SW	Metal	20	-21.0	6.5	5	1.80
(l)	[34]	BV SW	Thickness	20	-23.9	7.2	5.5	1.845
(m)	[3,37]	BV SW	Thickness	20	-29.8	7.2	5.5	1.845
(n)	[29]	FV SW	Thickness	20	-7.3	6.2	100	2.030
(o)	This paper	FV SW	Metal	8	-4.6	1.8	10.2	2.300

In contrast, one can note that the only other report using FV SW, shown as (n) [29], does not show a large depth of MBG because that study focused only on the spectral position of MBG, not on depth. Hence, introducing the noise suppression technique and 3D-designing technique shown in this paper will increase the depth. In addition, Fig. 6 does not consider the observed frequency, applied field, properties of YIG, and measurement setup (i.e., the dynamic range of the network analyzer). This accounts for the large deviation displayed in the figure.

The simplest way to maximize the depth of MBG is to maximize the number of structures, and the maximum value can be determined by the propagation length of SWs. Therefore, to increase the depth of MBG, the suppression of insertion losses of the input and output ports using an impedance-matching technique and/or meander antenna should be effective. In addition, decreasing the damping factor of the SW waveguide material (including YIG) and its in-plane uniformity, and development of a precise nano- or micropatterning procedure for YIG would also help increase the propagation length of SWs and the depth of MBG.

IV. CONCLUSION

A 1D MC is demonstrated using Cu stripes fabricated on $10.2\text{-}\mu\text{m}$ -thick YIG film based on FV SWs. This is a report of MBG for FV SWs using a periodically metallized YIG waveguide. The MBG is designed by combining magnetostatic equations and the FIT using a 3D model. At $f = 1.80$ GHz, a MBG with a depth of approximately -4.6 dB is observed experimentally, which is close to the depth of -3.3 dB observed in the simulation. The calculated results demonstrate the importance of

the SW absorber in order to obtain a distinct MBG. This is an important component for controlling FV SWs when realizing SW ICs in the future.
