#### Abstract

Consider a setting where a single bit is broadcast down the $d$-ary tree, where each edge acts as a binary symmetric channel with a crossover probability $\delta$. The goal is to reconstruct the root bit given the values of all bits at a large distance $h$ from the root. It is known the reconstruction is impossible iff $(1-2 \delta)^{2} d \leq 1$. In this paper, we show that in the regime where the latter product converges to 1 from the above, the distribution of the log-likelihood ratio (LLR) of the root bit given the far-away boundary (normalized by the square root of deviation of $\delta$ from criticality) converges to an explicit Gaussian distribution. This strengthens a similar result of Jain-Koehler-Liu-Mossel (COLT'2019) and enables us to resolve conjectures stated in Gu-Roozbehani-Polyanskiy (ISIT'2020) for the scaling of the probability of error and mutual information near criticality. Our results also provide a rationale for the ubiquitous $\mathcal{N}(\mu, 2 \mu)$ approximation of the LLR distribution in the EXITchart heuristics.

## I. Introduction

We consider an infinite perfect $d$-ary tree with a root called vertex 0 . Each vertex $v$ is associated with a binary variable $X_{v} . X_{0}$ is $\operatorname{Bernoulli}\left(\frac{1}{2}\right)$. For any vertex $v \neq 0$, let $u$ be its parent, $X_{v}$ equals $X_{u}$ with a probability of $1-\delta$ and $1-X_{u}$ otherwise, conditioned on the collection of $X_{v}^{\prime}$ for all vertices $v^{\prime} \neq v$ with a level less or equal to than the level of $v$, for some parameter ${ }^{1} \delta \in\left(0, \frac{1}{2}\right]$.

Let $L_{h}$ denotes the collection of vertices with a level of $h$, let $X_{L_{h}}$ denotes the collection of $X_{v}$ for any $v \in L_{h}$. We are interested in the following two lists of quantities: $P(\delta, h)$ defined as the minimum probability of error for estimating $X_{0}$ using $X_{L_{h}}$; and $I(\delta, h) \triangleq I\left(X_{0} ; X_{L_{h}}\right)$. We aim to solve for $P(\delta) \triangleq \lim _{h \rightarrow+\infty} P(\delta, h)$ and $I(\delta) \triangleq \lim _{h \rightarrow+\infty} I(\delta, h)$.

It is known from [1]-[3] that there is a reconstruction threshold $\delta_{\mathrm{c}}=\frac{1-\frac{1}{\sqrt{d}}}{2}$ such that $P(\delta)=\frac{1}{2}$ (or equivalently, $I(\delta)=0$ ) if and only if $\delta \geq \delta_{\mathrm{c}}$. However, the values of $I(\delta)$ and $P(\delta)$ are not known for $\delta<\delta_{\mathrm{c}}$. Some conjectures about the limiting behavior of these quantities as $\delta \rightarrow \delta_{\mathrm{c}}$ were stated in [4] on their decay rates and the associated multiplicative factors. In this work, we resolve those conjectures by characterizing the belief propagation (BP) fixed point distribution in this limit.

We note that a generalization of the basic setting was considered in [5], referred to as "robust reconstuction", where instead of inferring $X_{0}$ from $X_{L_{h}}$, a noisy version of the latter is observed with entries corrupted by independent and identical discrete channels. All results presented in this paper

[^0]directly apply to the robust reconstruction as long as the observation channels are symmetric (or BMS [6, Chapter 4]). While we focus on a symmetric setting, broadcasting through asymmetric channels has also been studied. E.g., the first tight result is provided in [7], matching the Kesten-Stigum lower bound [2] on reconstruction threshold.

For convenience, we define $\tau=\delta_{\mathrm{c}}-\delta$. Note that $\tau \rightarrow 0^{+}$ and $\delta \rightarrow \delta_{\mathrm{c}}^{-}$are equivalent for any fixed $d$.

## A. BP recursion

To find the values of $P(\delta)$ and $I(\delta)$, we need to introduce distributional BP recursion equations. To that end, define loglikelihood ratio (LLR) distribution conditioned on $X_{0}=0$ as

$$
\mathbb{P}\left[R_{(h)}=r\right]=\mathbb{P}\left[\left.\ln \frac{P\left(X_{L_{h}} \mid X_{0}=0\right)}{P\left(X_{L_{h}} \mid X_{0}=1\right)}=r \right\rvert\, X_{0}=0\right]
$$

For $h=0$ we set $R_{(0)}=+\infty$ w.p. 1. It is easy to check that the law $\mu$ of $R_{(h)}$ for any $h$ satisfies the following symmetry condition:

$$
\begin{equation*}
d \mu(r)=e^{r} d \mu(-r) \tag{1}
\end{equation*}
$$

which for a discrete distribution is equivalent to $\mathbb{P}\left[R_{(h)}=\right.$ $r]=e^{r} \mathbb{P}\left[R_{(h)}=-r\right]$.

The distribution of $R_{(h)}$ can be determined recursively, as follows. Let $\tilde{R}_{u}$ be iid copies of $R_{(h)}$ and let $X_{u} \stackrel{i i d}{\sim}(-1)^{\operatorname{Ber}(\delta)}$ (all jointly indepenent). Then

$$
R_{(h+1)} \stackrel{(d)}{=} \sum_{u=1}^{d} X_{u} F_{\delta}\left(\tilde{R}_{u}\right)
$$

where

$$
F_{\delta}(x) \triangleq \ln \frac{(1-\delta) e^{x}+\delta}{\delta e^{x}+1-\delta}=2 \tanh ^{-1}\left((1-2 \delta) \tanh \frac{x}{2}\right)
$$

(The same recursion works for the robust reconstruction problem, except that $R_{(0)}$ is taken to be any general symmetric distribution, cf. (1).)

Knowing $R_{(h)}$, one can express quantities of interest as follows.

$$
\begin{align*}
P(\delta, h) & =\mathbb{P}\left[R_{(h)}<0\right]+\frac{1}{2} \mathbb{P}\left[R_{(h)}=0\right]  \tag{2}\\
I(\delta, h) & =\ln 2-\mathbb{E}\left[\ln \left(1+e^{\left.-R_{(h)}\right)}\right)\right] \tag{3}
\end{align*}
$$

Hence, to solve for $P(\delta)$ and $I(\delta)$, it suffices to characterize the distribution of $R_{(h)}$.

As $h \rightarrow \infty$ it is known that the distributions of $R_{(h)}$ converge to a distribution with the following general properties.

Definition 1 (Fixed point of BP). A distribution $\mu$ is called a BP fixed point if given $\tilde{R}_{u} \stackrel{i i d}{\sim} \mu$ and $X_{u} \stackrel{i i d}{\sim}(-1)^{(\operatorname{Ber}(\delta)}$ (jointly independetly of each other) we have that

$$
R \triangleq \sum_{u=1}^{d} X_{u} F_{\delta}\left(\tilde{R}_{u}\right)
$$

also has law $\mu$. Furthermore, we call a fixed point symmetric if $\mu$ satisfies (1) and non-trivial if $\mu[\{0\}]<1$.

The following is well known (e.g. [8, Lemma 29]):
Proposition 1. For each $\tau$ the distributions of $R_{(h)}$ converge to a symmetric fixed point distribution $\mu_{\tau}^{*}$, which is nontrivial iff $\tau>0$. The same statement holds for the robust reconstruction problem with symmetric noise channels (with positive capacities) at the leaves.

## II. Main Results

Our goal is to provide new statements about the mysterious measures $\mu_{\tau}^{*}$ (cf. Proposition 1) in the limit of $\tau \rightarrow 0^{+}$. It is widely believed that for each $\tau>0$ there is a unique non-trivial symmetric fixed point $\mu_{\tau}$, however, at present this is only proved for $d(1-2 \delta)^{2}>3.531$, cf. [9]. We prove, however, that unconditionally, any sequence of fixed-points $\mu_{\tau}$ must be asymptotically Gaussian. We remind the reader of the definition of a normal family, see Chapter 8.4.2 in [10].

Theorem 1. For any fixed $d$ and for each $\tau$, let $\mu_{\tau}$ be any nonzero symmetric solution to the fixed point equation. Consider $R_{\tau} \sim \mu_{\tau}$ and let $A_{\tau}=R_{\tau} / \sqrt{\tau}$. The set of holomorphic functions $z \mapsto \mathbb{E}\left[e^{z A_{\tau}}\right]$ indexed by $\tau \in\left(0, \tau_{0}\right)$ for any $\tau_{0}<\delta_{\mathrm{c}}$ is uniformly bounded on any strip $\{z:|\Re(z)|<h\}$. In particular, this set forms a normal family on all of $\mathbb{C}$. Furthermore, we have

$$
\begin{equation*}
\mathbb{E}\left[e^{z A_{\tau}}\right] \rightarrow e^{\sigma^{2} z^{2} / 2} \quad\left(\text { as } \tau \rightarrow 0^{+}\right) \tag{4}
\end{equation*}
$$

uniformly on compacts, where $\sigma^{2}=\lim _{\tau \rightarrow 0^{+}} \frac{\mathbb{E}\left[R_{\tau}^{2}\right]}{\tau}=\frac{16 d \sqrt{d}}{d-1}$.
Our result imply that random variables $\frac{R_{\tau}}{\sqrt{\tau}}$ converge to Gaussian in distribution, and in terms of moments of all orders. We remark that previously asymptotic normality was shown in Corollary 4 of [8], albeit under a weaker mode of convergence (Wasserstein distance) and only for the special sequence $\mu_{\tau}^{*}$. Instead, our result applies to any BP-fixed point, and in particular, establishes asymptotic normality in the problem of robust reconstruction [5].

Corollary 1 (First-Order Approximations). The mutual information and probability of error are characterized by

$$
\begin{align*}
I(\delta) & =\frac{2 d \sqrt{d}}{d-1} \tau+o(\tau)  \tag{5}\\
P(\delta) & =\frac{1}{2}-\sqrt{\frac{2 d \sqrt{d}}{\pi(d-1)}} \sqrt{\tau}+o(\sqrt{\tau}) \tag{6}
\end{align*}
$$

We compare the obtained approximations with their numerical values in Fig. 1. The first-order approximations approach the numerical values as $\tau \rightarrow 0^{+}$. To further reduce the
gaps, we present in [11] that the distribution of $R$ can be approximated using a sequence of density functions, which proves that $I(\delta)$ and $P(\delta)$, as well as expectations of general functions of $R_{\tau}$, possess some asymptotic expansions. We also provide systematic approaches for computing them.

Fig. 1: Comparison between the first-order approximations and the numerical values, for $I(\delta)$ and $P(\delta)$.

Remark 1. Theorem 1 states that $\mathcal{N}\left(0, \tau \sigma^{2}\right)$ approximates the distribution of $R_{\tau}$. However, this distribution does not satisfy (1). Its symmetrized version would be $\mathcal{N}\left(\frac{\tau}{2} \sigma^{2}, \tau \sigma^{2}\right)$, as often used in the EXIT-chart method [6, Section 4.10]. Table I shows that moments of the latter indeed better approximate moments of $R_{\tau}=\sqrt{\tau} A_{\tau}$. In fact, in [11] we generalize this result by showing that, while $\mathbb{E}\left[R_{\tau}^{2 k}\right] \asymp \tau^{k}$, the $2 k$-th cumulant $\kappa_{2 k}\left(R_{\tau}\right) \asymp \tau^{2 k-1}$ decaying at twice the speed.

| Distributions | $2 k$-th moment | $(2 k-1)$-th moment |
| :--- | :---: | :---: |
| $\mathcal{N}\left(0, \tau \sigma^{2}\right)$ | $\tau^{k} \sigma^{2 k}(2 k-1)!!$ | 0 |
| $\mathcal{N}\left(\frac{\tau}{2} \sigma^{2}, \tau \sigma^{2}\right)$ | $\tau^{k} \sigma^{2 k}(2 k-1)!!+o\left(\tau^{k+1}\right)$ | $\frac{\tau^{k} \sigma^{2 k}(2 k-1)!!}{2}+o\left(\tau^{k+1}\right)$ |
| $R_{\tau}$ | $\tau^{k} \sigma^{2 k}(2 k-1)!!+o\left(\tau^{k+1}\right)$ | $\frac{\tau^{k} \sigma^{2 k}(2 k-1)!!}{2}+o\left(\tau^{k+1}\right)$ |

TABLE I: A comparison of moments of different distributions.
Remark 2. The Gaussian convergence is intuitive from the fixed point equation. Note that $F_{\delta}(R)$ is approximately linear when $R$ is small. Particularly, $F_{\delta}(R)=R / \sqrt{d}+O\left(\tau R+R^{3}\right)$. Hence, by approximating it using the linear term $R / \sqrt{d}$, and assuming $R \stackrel{(d)}{\approx}-R$ from the symmetry condition. The fixed point equation gives the following for any $k$,

$$
R \stackrel{(d)}{\approx} \frac{\sum_{u=1}^{d} \tilde{R}_{u}}{\sqrt{d}} \stackrel{(d)}{\approx} \frac{\sum_{u=1}^{d^{k}} \tilde{R}_{u}}{\sqrt{d^{k}}}
$$

leading to normal distributions by central limit theorem.

## III. Proof of Gaussian limit

We prove Theorem 1 and Corollary 1 in this section. We denote by $R_{\tau}$ a random variable with distribution $\mu_{\tau}$, which is a non-trivial symmetric BP fixed point. The notation $o(1)$, $O(1), O\left(\tau^{k}\right)$ etc all refer to the regime of $\tau \rightarrow 0^{+}$.

## A. Convergence of moments

To demonstrate the main proof ideas, we first compute the 0 -th order expansion and also show applicability of Taylor series expansion. I.e. we show that as $\tau \rightarrow 0, \mathbb{E}\left[R_{\tau}^{2}\right]=o(1)$ and $\mathbb{E}\left[R_{\tau}^{2 k}\right]=O\left(\mathbb{E}\left[R_{\tau}^{2}\right]^{k}\right)$, making Taylor series expansion convergent (this is what is known as "perturbation theory" in
physics). Note that $F_{\delta}$ is bounded, any solution to the fixed point equation is also bounded. More precisely, we have the following proposition.

Proposition 2 (Boundedness of $R$ ). The distribution of $R_{\tau}$ satisfies

$$
\begin{equation*}
\mathbb{P}\left[\left|R_{\tau}\right| \leq R_{\mathbb{1}}\right]=1 \tag{7}
\end{equation*}
$$

where $R_{\mathbb{1}} \triangleq d \ln \frac{1-\delta}{\delta}=O(1)$.
Hence, $\mathbb{E}\left[f\left(R_{\tau}\right)\right]$ is well-defined for any bounded Borel $f$. We also have the following rules by symmetry condition.
Proposition 3 (Symmetrization and comparison rules). For any bounded Borel $f:\left[-R_{\mathbb{1}}, R_{\mathbb{1}}\right] \rightarrow \mathbb{R}$ we have

$$
\begin{equation*}
\mathbb{E}\left[f\left(R_{\tau}\right)\right]=\mathbb{E}\left[\frac{e^{\frac{1}{2} R_{\tau}} f\left(R_{\tau}\right)+e^{-\frac{1}{2} R_{\tau}} f\left(-R_{\tau}\right)}{e^{\frac{1}{2} R_{\tau}}+e^{-\frac{1}{2} R_{\tau}}}\right] \tag{8}
\end{equation*}
$$

In particular, for any odd function $f$ we have $\mathbb{E}\left[f\left(R_{\tau}\right)\right]=$ $\mathbb{E}\left[f\left(R_{\tau}\right) \tanh \frac{R_{\tau}}{2}\right]$. Consequently, if $f$ and $g$ are two odd functions with $f \geq g$ on $\left[0, R_{\mathbb{1}}\right]$ then

$$
\begin{equation*}
\mathbb{E}\left[f\left(R_{\tau}\right)\right] \geq \mathbb{E}\left[g\left(R_{\tau}\right)\right] \tag{9}
\end{equation*}
$$

Proof. Let $\tilde{f}\left(R_{\tau}\right) \triangleq \frac{e^{-\frac{1}{2} R_{\tau}} f\left(R_{\tau}\right)}{e^{\frac{1}{2} R_{\tau}}+e^{-\frac{1}{2} R_{\tau}}}$. Equation (8) is implied by $\mathbb{E}\left[\tilde{f}\left(R_{\tau}\right)\right]=\mathbb{E}\left[\tilde{f}\left(-R_{\tau}\right) e^{-R_{\tau}}\right]$, which is due to the symmetry condition of $\mu_{\tau}$.

We start by showing a simple result characterizing the reconstruction threshold $\delta_{c}$.
Lemma 1. For $\tau<0$ we have $\mathbb{E}\left[R_{\tau}^{2}\right]=0$, for $\tau>0$ we have $\mathbb{E}\left[R_{\tau}^{2}\right]=o(1)$ as $\tau \rightarrow 0+$.

Proof. According to the fixed point equation, by taking the expectation of $R$,

$$
\begin{equation*}
\mathbb{E}\left[R_{\tau}\right]=d(1-2 \delta) \mathbb{E}\left[F_{\delta}\left(R_{\tau}\right)\right] \tag{10}
\end{equation*}
$$

Note that $F_{\delta}$ is an odd function, and it is easy to show that due to (7):

$$
F_{\delta}\left(R_{\tau}\right) \leq F_{\delta}^{\prime}(0) R_{\tau}-c R_{\tau}^{3}=(1-2 \delta) R_{\tau}-c R_{\tau}^{3}
$$

for $c=\frac{1-2 \delta}{6} \min \left\{\delta(1-\delta), \frac{1}{R_{\mathbb{1}}^{2}}\right\}$. Together with (10) we get

$$
\mathbb{E}\left[R_{\tau}\right] \leq d(1-2 \delta)^{2} \mathbb{E}\left[R_{\tau}\right]-c \mathbb{E}\left[R_{\tau}^{3}\right]
$$

By symmetrization, we have $\mathbb{E}\left[R_{\tau}^{3}\right]=\mathbb{E}\left[R_{\tau}^{3} \tanh \left(\frac{1}{2} R_{\tau}\right)\right] \geq$ $\frac{1-2 \delta}{R_{1}} \mathbb{E}\left[R_{\tau}^{4}\right] \geq \frac{1-2 \delta}{R_{1}} \mathbb{E}\left[R_{\tau}^{2}\right]^{2}$. Hence,

$$
\mathbb{E}\left[R_{\tau}\right] \leq d(1-2 \delta)^{2} \mathbb{E}\left[R_{\tau}\right]-c(1-2 \delta) \frac{\mathbb{E}\left[R_{\tau}^{2}\right]^{2}}{R_{\mathbb{1}}}
$$

which is, equivalently,

$$
\left((1-2 \delta)^{2}-\frac{1}{d}\right) \mathbb{E}\left[R_{\tau}\right] \geq c(1-2 \delta) \frac{\mathbb{E}\left[R_{\tau}^{2}\right]^{2}}{R_{\mathbb{1}}}
$$

Because $\mathbb{E}\left[R_{\tau}\right] \geq 0$ (e.g. from (9)), if $(1-2 \delta)^{2}-\frac{1}{d} \leq 0$, i.e., $\delta \geq \delta_{\mathrm{c}}$, we have $\mathbb{E}\left[R_{\tau}^{2}\right]=0$. This corresponds to the case that $I(\delta)=0$ and $P(\delta)=\frac{1}{2}$, recovering the well known reconstructability result. When $\tau>0$ we have $(1-2 \delta)^{2}-\frac{1}{d} \asymp$ $\tau$, yielding $\mathbb{E}\left[R_{\tau}^{2}\right]=O(\sqrt{\tau})=o(1)$.

For higher moments, the results are obtained similarly by expanding the expectation of $R_{\tau}^{2 k}$ using the fixed point equation.

Lemma 2. For $\tau \rightarrow 0^{+}$and any integer $k>0$, we have

$$
\begin{equation*}
\mathbb{E}\left[R_{\tau}^{2 k}\right]=O\left(\mathbb{E}\left[R_{\tau}^{2}\right]^{k}\right) \tag{11}
\end{equation*}
$$

Furthermore, we have

$$
\begin{equation*}
\mathbb{E}\left[R_{\tau}^{2 k}\right]=(2 k-1)!!\mathbb{E}\left[R_{\tau}^{2}\right]^{k}(1+o(1)) \tag{12}
\end{equation*}
$$

Proof. We prove Lemma 2 by induction. The $k=1$ case is trivial, so we focus on $k>1$.

We start by proving equation (11). For any $k>1$, we evaluate $\mathbb{E}\left[R_{\tau}^{2 k}\right]$ using the fixed point equation.

$$
\begin{align*}
\mathbb{E}\left[R_{\tau}^{2 k}\right]= & \mathbb{E}\left[\left(\sum_{u=1}^{d} X_{u} F_{\delta}\left(\tilde{R}_{u}\right)\right)^{2 k}\right] \\
= & \sum_{m_{1}+m_{2}+\ldots+m_{d}=2 k}\binom{2 k}{m_{1}, \ldots, m_{d}} \\
& \prod_{u=1}^{d} \mathbb{E}\left[\left(X_{u} F_{\delta}\left(\tilde{R}_{u}\right)\right)^{m_{u}}\right] \tag{13}
\end{align*}
$$

From $F_{\delta}(x) \leq(1-2 \delta) x$ for $x>0$ we obtain for any even $m$ :

$$
\begin{equation*}
\mathbb{E}\left[\left(X_{u} F_{\delta}\left(\tilde{R}_{u}\right)\right)^{m}\right] \leq(1-2 \delta)^{m} \mathbb{E}\left[R_{\tau}^{m}\right] \tag{14}
\end{equation*}
$$

Consequently, from the induction hypothesis, every term in (13) with $m_{u}$-even and $<2 k$ is of order $\mathbb{E}\left[R_{\tau}^{2}\right]^{k}$. We next show that all other terms with all $m_{u}<2 k$ are $o\left(\mathbb{E}\left[R_{\tau}^{2}\right]^{k}\right)$ or $o\left(\mathbb{E}\left[R_{\tau}^{2 k}\right]\right)$. First, we notice the estimate for any odd $m$ via (8):

$$
\begin{align*}
\mathbb{E}\left[\left(X_{u} F_{\delta}\left(\tilde{R}_{u}\right)\right)^{m}\right] & =(1-2 \delta) \mathbb{E}\left[\left(F_{\delta}\left(R_{\tau}\right)\right)^{m} \tanh \frac{R_{\tau}}{2}\right] \\
& =O\left(\mathbb{E}\left[R_{\tau}^{m+1}\right]\right) \tag{15}
\end{align*}
$$

Next, consider terms where $m_{u}=2 k-1$ (and thus some other $m_{u^{\prime}}=1$ ). For such terms, we have $\prod_{u} \mathbb{E}\left[R_{\tau}^{m_{u}}\right]=$ $O\left(\mathbb{E}\left[R_{\tau}^{2 k}\right] \mathbb{E}\left[R_{\tau}^{2}\right]\right)$ which is $o\left(\mathbb{E}\left[R_{\tau}^{2 k}\right]\right)$ via Lemma 1. Next, consider terms with all $m_{u}<2 k-1$. Then, for every odd $m_{u}$ from (15) and induction hypothesis we get $\mathbb{E}\left[R_{\tau}^{m_{u}+1}\right] \asymp$ $\mathbb{E}\left[R_{\tau}^{2}\right]^{\frac{m_{u}+1}{2}}$. Thus, taking the product of such terms we get overall order of $\mathbb{E}\left[R_{\tau}^{2}\right]$ to be strictly greater than $k$ (recall $\left.\sum_{u} m_{u}=2 k\right)$. Putting everything together, we obtained:

$$
\begin{align*}
& \mathbb{E}\left[R_{\tau}^{2 k}\right] \leq o\left(\mathbb{E}\left[R_{\tau}^{2 k}\right]\right)+o\left(\mathbb{E}\left[R_{\tau}^{2}\right]^{k}\right)+(1-2 \delta)^{2 k} \\
& \cdot \sum_{\substack{m_{1}+m_{2}+\ldots+m_{d}=2 k \\
2 \mid m_{u}, \forall u \in[d]}}\binom{2 k}{m_{1}, \ldots, m_{d}} \prod_{u=1}^{d} \mathbb{E}\left[R_{\tau}^{m_{u}}\right] . \tag{16}
\end{align*}
$$

We apply the induction assumption.

$$
\mathbb{E}\left[R_{\tau}^{2 k}\right] \leq(1-2 \delta)^{2 k} d \mathbb{E}\left[R_{\tau}^{2 k}\right]+O\left(\mathbb{E}\left[R_{\tau}^{2}\right]^{k}\right)+o\left(\mathbb{E}\left[R_{\tau}^{2 k}\right]\right)
$$

Recall that $\mathbb{E}\left[R_{\tau}^{2}\right]=o(1)$.

$$
\begin{align*}
\mathbb{E}\left[R_{\tau}^{2 k}\right] \leq & \frac{1}{1-(1-2 \delta)^{2 k} d-O\left(\mathbb{E}\left[R_{\tau}^{2}\right]\right)} O\left(\mathbb{E}\left[R_{\tau}^{2}\right]^{k}\right) \\
& =O\left(\mathbb{E}\left[R_{\tau}^{2}\right]^{k}\right) \tag{17}
\end{align*}
$$

To prove (12), we can rederive (16) as equality by improving (14). Indeed, it is easy to show that due to (7) we have $F_{\delta}\left(R_{\tau}\right)=(1-2 \delta) R_{\tau}+c\left(R_{\tau}\right) R_{\tau}^{3}$ where $\left|c\left(R_{\tau}\right)\right|$ is bounded. By raising this identity to the even power $m$ and repeatedly applying (11) we obtain

$$
\begin{align*}
\mathbb{E}\left[\left(X_{u} F_{\delta}\left(\tilde{R}_{u}\right)\right)^{m}\right] & =\mathbb{E}\left[F_{\delta}\left(\tilde{R}_{u}\right)^{m}\right]=(1-2 \delta)^{m} \mathbb{E}\left[R_{\tau}^{m}\right](1+o(1)) \\
& =\left(\frac{1}{\sqrt{d}}\right)^{m} \mathbb{E}\left[R_{\tau}^{m}\right](1+o(1)) \tag{18}
\end{align*}
$$

Consequently, we obtain the following expression for $\mathbb{E}\left[R_{\tau}^{2 k}\right]$ :

$$
\sum_{\substack{m_{1}+\ldots+m_{d}=2 k \\ 2 \mid m_{u}, \forall u \in[d]}}\binom{2 k}{m_{1}, \ldots, m_{d}} \prod_{u=1}^{d} \mathbb{E}\left[\left(\frac{R_{\tau}}{\sqrt{d}}\right)^{m_{u}}\right](1+o(1))
$$

Now consider a Gaussian variable $G \sim \mathcal{N}\left(0, \mathbb{E}\left[R_{\tau}^{2}\right]\right)$. Then by infinite divisibility of the Gaussian we have

$$
\begin{equation*}
\mathbb{E}\left[G^{2 k}\right]=\mathbb{E}\left[\left(\frac{G_{1}}{\sqrt{d}}+\cdots+\frac{G_{d}}{\sqrt{d}}\right)^{2 k}\right] \tag{19}
\end{equation*}
$$

Since odd moments $\mathbb{E}\left[G^{m}\right]=0$ after expanding the power, we obtain exactly the same expansion as the dominant terms for $\mathbb{E}\left[R_{\tau}^{2 k}\right]$. Since by the induction assumption we already know $\mathbb{E}\left[R_{\tau}^{2 k_{1}}\right]=\mathbb{E}\left[G^{2 k_{1}}\right](1+o(1))$ for all $k_{1}<k$, we conclude that also

$$
\mathbb{E}\left[R_{\tau}^{2 k}\right]=\mathbb{E}\left[G^{2 k}\right](1+o(1))=(2 k-1)!!\mathbb{E}\left[R_{\tau}^{2}\right]^{k}(1+o(1))
$$

## B. First-Order Approximation

Lemma 3. For $\tau<0$ we have $\mathbb{E}\left[R_{\tau}^{2}\right]=0$. For $\tau \rightarrow 0+$ we have $\mathbb{E}\left[R_{\tau}^{2}\right]=O(\tau)$, and more precisely,

$$
\begin{equation*}
\mathbb{E}\left[R_{\tau}^{2}\right]=\frac{16 d \sqrt{d} \tau}{d-1}+o(\tau) \tag{20}
\end{equation*}
$$

Remark 3. The fact that $\mathbb{E}\left[R_{\tau}^{2}\right] \asymp \tau$ can be guessed as follows. Note that there is a $r^{*}(\tau)>0$ such that $\left|F_{\delta}(R)\right|>|R / \sqrt{d}|$ $\Longleftrightarrow|R|<r^{*}(\tau)$. Hence, the nonlinearity of $F_{\delta}(R)$ favors further reducing $\mathbb{E}\left[R_{\tau}^{2}\right]$ when $\left|R_{\tau}\right|$ is large, and vice versa. As a consequence, the scale of $R_{\tau}$ tends to be stabilized at $r^{*}(\tau)$, which is at the level of $\sqrt{\tau}$.

Proof. We use the fixed point equation to evaluate the second moment.

$$
\mathbb{E}\left[R_{\tau}^{2}\right]=d \mathbb{E}\left[F_{\delta}\left(R_{\tau}\right)^{2}\right]+d(d-1)\left((1-2 \delta) \mathbb{E}\left[F_{\delta}\left(R_{\tau}\right)\right]\right)^{2}
$$

By expanding and approximating $F_{\delta}$ with Lemma 2 and symmetrization, we can express both $\mathbb{E}\left[F_{\delta}\left(R_{\tau}\right)\right]^{2}$ and $\mathbb{E}\left[F_{\delta}\left(R_{\tau}\right)^{2}\right]$ using $\mathbb{E}\left[R_{\tau}^{2}\right]$, with an error term up to $o\left(\mathbb{E}\left[R_{\tau}^{2}\right]^{2}\right)$.

$$
\begin{aligned}
\mathbb{E}\left[F_{\delta}\left(R_{\tau}\right)\right]^{2}= & \frac{(1-2 \delta)^{2}}{4} \mathbb{E}\left[R_{\tau}^{2}\right]^{2}+o\left(\mathbb{E}\left[R_{\tau}^{2}\right]^{2}\right) \\
\mathbb{E}\left[F_{\delta}\left(R_{\tau}\right)^{2}\right]= & (1-2 \delta)^{2}\left(\mathbb{E}\left[R_{\tau}^{2}\right]-2 \delta(1-\delta) \mathbb{E}\left[R_{\tau}^{2}\right]^{2}\right) \\
& +o\left(\mathbb{E}\left[R_{\tau}^{2}\right]^{2}\right)
\end{aligned}
$$

Then by $d(1-2 \delta)^{2}=1+o(1)$, we have

$$
\begin{equation*}
\left(d(1-2 \delta)^{2}-1\right) \mathbb{E}\left[R_{\tau}^{2}\right]=\frac{(d-1)}{4 d} \mathbb{E}\left[R_{\tau}^{2}\right]^{2}(1+o(1)) \tag{21}
\end{equation*}
$$

Recall the non-zero requirement. We have $\mathbb{E}\left[R_{\tau}^{2}\right]>0$. Then the above quadratic equation implies that

$$
\begin{aligned}
\mathbb{E}\left[R_{\tau}^{2}\right] & =\frac{4 d}{d-1}\left(d(1-2 \delta)^{2}-1\right)(1+o(1)) \\
& =\frac{16 d \sqrt{d} \tau}{d-1}+O(\tau)
\end{aligned}
$$

## C. Subgaussianity of $\frac{R_{\tau}}{\sqrt{\tau}}$

Theorem 1 also relies on the following final ingredient.
Lemma 4. In the conditions of Theorem 1, define $M_{R_{\tau}}(s)=$ $\mathbb{E}\left[e^{s R_{\tau}}\right]$. Then $\forall \delta_{0} \in\left(0, \delta_{\mathrm{c}}\right)$, there are $C_{1}, C_{2}>0$ such that for any $z \in \mathbb{C}$ and $\tau<\delta_{\mathrm{c}}-\delta_{0}$, we have

$$
\left|M_{R_{\tau}}(z / \sqrt{\tau})\right| \leq C_{1} \exp \left(C_{2} \Re\{z\}^{2}\right)
$$

Proof. Recall the definition of moment-generating functions. We have $\left|M_{R_{\tau}}(z / \sqrt{\tau})\right| \leq M_{R_{\tau}}(\Re\{z\} / \sqrt{\tau})$. It suffices to prove for the case where $z \in \mathbb{R}$.

We first prove the following unconditional estimate. For every $s \in \mathbb{R}$ and integer $r \in \mathbb{N}$ :

$$
\begin{equation*}
\ln M_{R_{\tau}}(s) \leq d^{r} \ln M_{R_{\tau}}\left((1-2 \delta)^{r}|s|\right) \tag{22}
\end{equation*}
$$

By symmetrization, for any odd functions $f, g$, s.t. $f \geq|g|$ on $\mathbb{R}_{+}$, we have

$$
\begin{align*}
& \mathbb{E}\left[e^{f\left(R_{\tau}\right)}\right]-\mathbb{E}\left[e^{g\left(R_{\tau}\right)}\right]= \\
& \mathbb{E}\left[\frac{\cosh \left(\frac{R_{\tau}}{2}+f\left(R_{\tau}\right)\right)-\cosh \left(\frac{R_{\tau}}{2}+g\left(R_{\tau}\right)\right)}{\cosh \frac{R_{\tau}}{2}}\right] \geq 0 \tag{23}
\end{align*}
$$

Consequently, for any $s \geq 0, \mathbb{E}\left[e^{-s R_{\tau}}\right] \leq \mathbb{E}\left[e^{s R_{\tau}}\right]$, and $\mathbb{E}\left[e^{-s F_{\delta}\left(R_{\tau}\right)}\right] \leq \mathbb{E}\left[e^{s F_{\delta}\left(R_{\tau}\right)}\right] \leq \mathbb{E}\left[e^{s(1-2 \delta)} \bar{R}_{\tau}\right]$. In all, this implies

$$
\mathbb{E}\left[e^{s R_{\tau}}\right] \leq \mathbb{E}\left[e^{|s| F_{\delta}\left(R_{\tau}\right)}\right]^{d} \leq \mathbb{E}\left[e^{|s|(1-2 \delta) R_{\tau}}\right]^{d}
$$

By applying the above inequality recursively, we have for any integer $r \geq 0$,

$$
\begin{equation*}
\mathbb{E}\left[e^{s R_{\tau}}\right] \leq \mathbb{E}\left[\left|e^{|s|(1-2 \delta)^{r} R_{\tau}}\right|\right]^{d^{r}} \tag{24}
\end{equation*}
$$

which is essentially inequality (22).
Second, consider any $\delta_{0}$ bounded away from zero. Due to symmetrization and boundedness of $R$, we can uniformly upper bound $\ln M_{R_{\tau}}(s)$ for $|s| \leq 1$ by $O\left(\mathbb{E}\left[R_{\tau}^{2}\right]\right)$. In particular, we can find $c_{1}>0$ such that for any $\tau<\delta_{\mathrm{c}}-\delta_{0}$ and $|s| \leq 1$,

$$
\begin{equation*}
\ln M_{R_{\tau}}(s) \leq \ln \left(1+c_{1} \mathbb{E}\left[R_{\tau}^{2}\right]\right) \leq c_{1} \mathbb{E}\left[R_{\tau}^{2}\right] \tag{25}
\end{equation*}
$$

Then for general $|s| \in\left[1, \frac{1}{\tau}\right]$, the needed result for this regime can be obtained by applying inequality (22). Note that we can find integer $r$ such that $|s|(1-2 \delta)^{r} \leq 1$ with $r \leq$ $1+\frac{\ln |s|}{|\ln (1-2 \delta)|}$. By applying inequality (22), we have

$$
\ln M_{R_{\tau}}(s) \leq d^{\frac{\ln |s|}{\ln (1-2 \delta) \mid}+1} c_{1} \mathbb{E}\left[R_{\tau}^{2}\right]=\left\lvert\, s^{\frac{\ln d}{\ln (1-2 \delta) \mid}} c_{1} d \mathbb{E}\left[R_{\tau}^{2}\right]\right.
$$

Note that $\frac{\ln d}{|\ln (1-2 \delta)|} \leq 2+\frac{2 \sqrt{d}}{\left|\ln \left(1-2 \delta_{0}\right)\right|} \tau$. For any $|s| \in[1,1 / \tau]$,

$$
\begin{align*}
\ln M_{R_{\tau}}(s) & \leq e^{\frac{2 \sqrt{d}}{\mid \ln \left(1-2 \delta_{0}\right)} \tau|\ln \tau|} c_{1} d \mathbb{E}\left[R_{\tau}^{2}\right] s^{2} \\
& \leq e^{\frac{2 \sqrt{d}}{e \mid \ln \left(1-2 \delta_{0}\right)}} c_{1} d \mathbb{E}\left[R_{\tau}^{2}\right] s^{2} \tag{26}
\end{align*}
$$

Combining inequalities (25) and (26), there is $C>0$ such that for any $|s| \leq 1 / \tau$ and $\tau<\delta_{\mathrm{c}}-\delta_{0}$,

$$
\begin{equation*}
\ln M_{R_{\tau}}(s) \leq C \mathbb{E}\left[R_{\tau}^{2}\right]\left(1+s^{2}\right) \tag{27}
\end{equation*}
$$

Using the fact that $\mathbb{E}\left[R_{\tau}^{2}\right]=O(\tau)$ and $R_{\tau}$ is bounded, we can find $c_{2}, c_{3}>0$ such that for any $\tau<\delta_{\mathrm{c}}-\delta_{0}, \mathbb{E}\left[R_{\tau}^{2}\right] \leq c_{2} \tau$ and $R_{\mathbb{1}} \leq c_{3}$. Hence,

$$
\begin{equation*}
\ln M_{R_{\tau}}(s) \leq C\left(c_{3}+c_{2} s^{2} \tau\right) \tag{28}
\end{equation*}
$$

Finally, using the boundedness of $R$, for any $|s| \geq 1 / \tau$ and $\tau<\delta_{\mathrm{c}}-\delta_{0}$, we can find $R_{\mathbb{1}}<c$. Then,

$$
\begin{equation*}
\ln M_{R_{\tau}}(s) \leq \ln e^{c|s|} \leq c s^{2} \tau \tag{29}
\end{equation*}
$$

The proof is concluded by combining inequalities (28) and (29), which collectively cover the entire real line.

## D. Proofs of the Theorem and Corollary

Proof of Theorem 1. From Lemma 4, the family of functions $z \mapsto \mathbb{E}\left[e^{z A_{\tau}}\right]$ for any $\tau<\delta_{\mathrm{c}}-\delta_{0}$ is uniformly bounded on any compact subset of $\mathbb{C}$. Hence, they form a normal family on $\mathbb{C}$.

According to Lemma 2 and symmetry condition, all derivatives at zero of the moment-generating function $f_{\tau}(z)=$ $\mathbb{E}\left[e^{z A_{\tau}}\right]$ converge to those of $f(z)=e^{\frac{\sigma^{2} z^{2}}{2}}$, corresponding to $\mathcal{N}\left(0, \sigma^{2}\right)$. This implies that this family may have at most one limit point: $f(z)$. (Indeed, every limit point must be a holomorphic function itself by Cauchy's formula, with its Maclaurin series coinciding with that of $f$.) Suppose $f_{\tau} \nrightarrow$ $f$. Then on some compact $K \subset \mathbb{C}$ we have a sequence $\sup _{z \in K}\left|f_{\tau_{n}}(z)-f(z)\right| \geq \epsilon_{0}>0$ for all $n$. But by normality of the family, the subsequence $f_{\tau_{n}}$ must have a limit point and by the argument above it must be $f$, a contradiction.

We continue to characterize $I(\delta)$ and $P(\delta)$ for Corollary 1 using the proved Gaussian Convergence.

Proof of Corollary. By symmetrization rule and (3), we have

$$
\begin{equation*}
I(\delta)=\mathbb{E}\left[\frac{R_{\tau}}{2} \tanh \frac{R_{\tau}}{2}-\ln \cosh \frac{R_{\tau}}{2}\right] \tag{30}
\end{equation*}
$$

which is expectation of an even $C^{\infty}$ function of $R_{\tau}$. Using Lemma 2, it can be expanded and approximated using even moments of $R_{\tau}$.

$$
\begin{equation*}
I(\delta)=\frac{1}{8} \mathbb{E}\left[R_{\tau}^{2}\right]+O\left(\mathbb{E}\left[R_{\tau}^{4}\right]\right)=\frac{1}{8} \mathbb{E}\left[R_{\tau}^{2}\right]+O\left(\mathbb{E}\left[R_{\tau}^{2}\right]^{2}\right) \tag{31}
\end{equation*}
$$

Then equation (5) follow from Lemma 3.
For $P(\delta)$, first we need to show that it can be characterized as the expectation of a function of $R$. Because $P(\delta)$ is defined based on the expectation of a step function from a recursion process. Unlike $I(\delta)$, its connection to the limiting distribution
is not directly implied by weak convergence. This can be handled by applying symmetrization rule to the recursion, and we get

$$
\begin{equation*}
P(\delta)=\mathbb{E}\left[\frac{e^{-\frac{1}{2}\left|R_{\tau}\right|}}{e^{\frac{1}{2} R_{\tau}}+e^{-\frac{1}{2} R_{\tau}}}\right] \tag{32}
\end{equation*}
$$

Next, by expanding exponents in Taylor series (and using the uniform bound $\left|R_{\tau}\right|^{3} \leq C R_{\tau}^{2}$ for some constant $C>0$ ) we obtain

$$
\begin{equation*}
P(\delta)=\frac{1}{2}-\frac{\mathbb{E}\left[\left|R_{\tau}\right|\right]}{4}+O\left(\mathbb{E}\left[R_{\tau}^{2}\right]\right) \tag{33}
\end{equation*}
$$

Recalling that $R_{\tau}=\sqrt{\tau} A_{\tau}$, it suffices to find the 1st-order approximation for $\mathbb{E}\left[\left|A_{\tau}\right|\right]$. From Theorem 1 we know that the family $\left\{A_{\tau}, \tau \in\left(0, \tau_{0}\right)\right\}$ for any $\tau_{0}<\delta_{\mathrm{c}}$ is uniformly integrable. By Skorokhod representation we may assume $A_{\tau} \xrightarrow{(\text { a.s. })}$ $A_{0}=\mathcal{N}\left(0, \sigma^{2}\right)$. Then from uniform integrability we have $A_{\tau} \xrightarrow{L_{1}} A_{0}$ and, in particular, $\mathbb{E}\left[\left|A_{\tau}\right|\right] \rightarrow \mathbb{E}\left[\left|A_{0}\right|\right]=\sqrt{\frac{2 \sigma^{2}}{\pi}}$.

## IV. Higher-Order Corrections

In [11], we show that the distribution of $R$ can be approximated in a form of asymptotic expansions, up to any degree. In particular, we proved that all moments and cumulants of $R$ can be written into the forms of $C_{1} \tau^{k}+C_{2} \tau^{k+1}+\ldots$, where any of the coefficients can be computed as a closedform function of $d$. Moreover, we show that the cumulants of $R$ decay twice faster compared to the moments, providing a stronger characterization than Gaussian convergence. They imply the uniquness of the non-zero symmetric solutions to the fixed point equation near criticality up to an error term super-polynomial in $\tau$.

Generally, we prove the existence of a sequence of density functions, each simply given by a polynomial of $R$ multiplied by a normal density function, which can be used to approximate the expectation of any function of $R$ that is Lebesgue integrable on compact sets. In turn, these results imply higher-order expansions of $I(\delta)$ and $P(\delta)$, and provide better approximations near $\tau \rightarrow 0$, as illustrated in Fig 2.

Fig. 2: Comparison of approximation errors of different orders for $d=2$, defined as the difference between the truncated asymptotic expansions and the exact values. The data points for exact values are obtained numerically.
