Abstract

Title: Band Structure of Silver Chloride and Silver Bromide by the Augmented Plane Wave Method.

Author: Peter Michael Scop

The energy of silver chloride and silver bromide crystals has been calculated using the augmented plane wave method.

In this method one solves Schroedinger's equation for a periodic one electron potential in the crystal. In the augmented plane wave method, this potential is assumed to be ionic-like and spherically symmetric within spheres surrounding the ions, and constant in the region between spheres. Consequently, the wave function is expanded in a sum of free-ion functions within spheres and plane waves outside of the spheres. By varying the relative value of the constant potential between spheres, the size of the direct band gap at  $k = 0$  has been fit to the experimental value.

After considering non-spherical cubic field effects within the spheres and relativistic effects (including spin-orbit coupling), the calculated magnitude of the indirect band gap is found to agree quite well with experiment. The indirect band gap arises from electronic transitions from the highest point in the valence band (the point  $L_3$  at  $k = \frac{\pi}{a} (1,1,1)$  for both crystals) to the lowest point in the conduction band at  $k = 0$ .

Selection rules for both direct and indirect transitions (with and without spin) have been derived.

### Acknowledgments

The author wishes to thank Professor John Wood under whose supervision this work was performed. He also wishes to thank the members of the Solid State and Molecular Theory Group of M. I. T. for their discussions and assistance, especially Dr. A. C. Switendick who supplied virtually all of the necessary computer programs.

In addition he thanks James Conklin of the M. I. T. Electrical Engineering Department who also lent his advice and criticisms as well as some of the computer programs.

Many thanks are given to the staff of the Cooperative Computer Laboratory for their help and tolerance.

Finally, he wishes to thank the Graduate Committee for the teaching and research assistantships held by him during his period as a graduate student.

## Chapter I

### APW Calculations

#### I-1. Introduction.

The Augmented Plane Wave Method (henceforth abbreviated APW) was employed in calculating the electronic band structure of silver chloride and silver bromide crystals. This method was originally proposed by Slater<sup>1</sup> and later used by Wood<sup>2</sup> in his calculation of the band structure of iron. More recently, Switendick<sup>3</sup> has extended the method to deal with problems involving two atoms per unit cell in his band calculations of nickel oxide. This APW calculation of the band structure of silver chloride and silver bromide has been performed using the programs written by Wood and Switendick for the IBM 709 computer.

Briefly, the APW method takes advantage of the fact that the one-electron wave function is ionic-like near an ionic site and plane wave-like far from ionic sites. Consequently one inscribes spheres about each ion in the crystal; within each sphere we assume a spherically symmetric potential appropriate for the corresponding ion. In the region between spheres, we assume that the potential is equal to a constant,  $V_0$ . Corresponding to this choice of potential, the one electron wave function is expanded in APW's; that is, functions that are ionic-like inside the ionic spheres and plane wave-like outside of the spheres. Finally, the secular equation is obtained and, after taking advantage of the cubic symmetry, one obtains the eigenvalues.

Since the APW functions are constructed to correspond to the assumed potential, the convergence (the number of APW's needed to adequately represent a particular state) will be fairly rapid. However,

one must face some serious questions about the validity of the assumed potential.

The general form of this potential is sensible from physical reasoning, but the problem of choosing the various parameters entering into the calculations is a difficult one. Specifically, one must determine the sizes of the APW sphere radii and the constant value of the potential between spheres,  $V_0$ . In addition, the ionic potentials themselves usually depend on several parameters, especially the "ionicity" (the limit of  $\frac{r}{2}$  times the ionic potential, for large  $r$ ).

If one attempts to choose these parameters by physical reasoning, the results may be quite confusing. For example, in a real ionic crystal the previous simple definition of ionicity cannot even be applied since an electron never experiences a single ionic potential far from ionic sites. In addition, the concept of sphere radii may be misleading if there is any covalent bonding in the crystal.

In order to avoid these (and other) physical arguments, the present author has chosen the parameters in a rather arbitrary manner, and then varied one of them in order to obtain some agreement with experimental results.

I-2. Details of the calculations for AgBr and AgCl

AgBr and AgCl both have the NaCl structure; that is, two displaced face centered cubic lattices. One lattice composed of silver ions, the other containing the halogen ion.

In Figure I-1 we show the AgCl lattice. The silver ion is located at the origin of coordinates. The six neighboring chlorine ions are located at the points  $\pm \frac{a}{2} (1,0,0)$ ,  $\pm \frac{a}{2} (0,1,0)$ ,  $\pm \frac{a}{2} (0,0,1)$ . There are twelve nearest neighbor silver ions located at  $\pm \frac{a}{2} (1,1,0)$ ,  $\pm \frac{a}{2} (1,-1,0)$ ,  $\pm \frac{a}{2} (0,1,1)$ ,  $\pm \frac{a}{2} (0,1,-1)$ ,  $\pm \frac{a}{2} (1,0,1)$ ,  $\pm \frac{a}{2} (1,0,-1)$ . All translations which leave the lattice invariant are given by  $T_n = n_1 \vec{a}_1 + n_2 \vec{a}_2 + n_3 \vec{a}_3$  ( $n_1, n_2, n_3$  are integers) where  $\vec{a}_1, \vec{a}_2, \vec{a}_3$  are three primitive translations:

$$\vec{a}_1 = \frac{a}{2} (0,1,1)$$

$$\vec{a}_2 = \frac{a}{2} (1,0,1)$$

$$\vec{a}_3 = \frac{a}{2} (1,1,0)$$

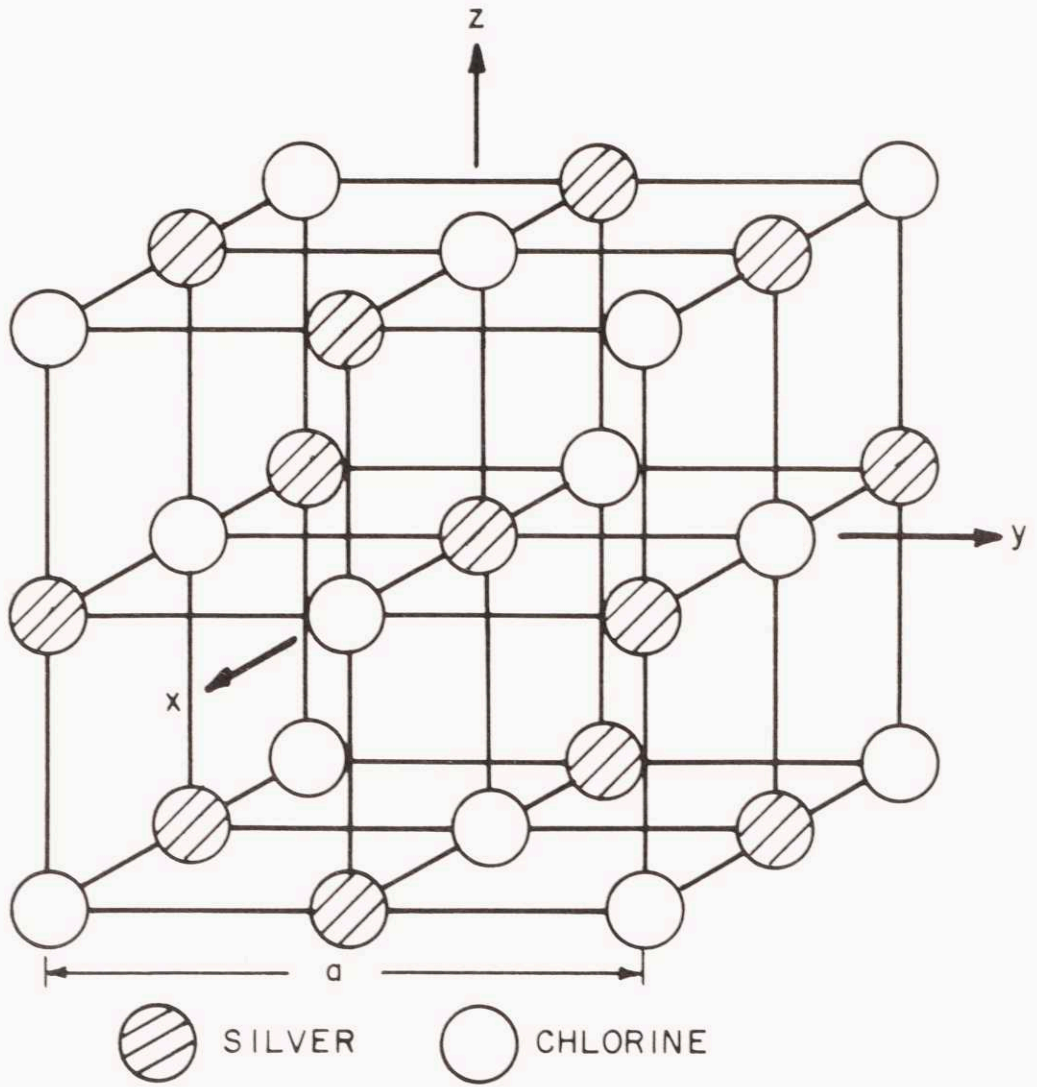

$$\text{For AgCl} \quad \frac{a}{2} = 5.23 \text{ atomic units.}$$

$$\text{AgBr} \quad \frac{a}{2} = 5.463 \text{ atomic units.}$$

The ionic potentials used are those determined by the Hartree-Fock-Slater equations and calculated using programs described by F. Herman and S. Skillman.<sup>4</sup> That is, for a particular ion,

Figure I-1

SILVER CHLORIDE LATTICE

$$V(r) = \frac{-2Z}{r} - \frac{2}{r} \int_0^r \sigma(t) dt - 2 \int_r^\infty \frac{\sigma(t)}{t} dt - 6 \left[ \frac{-3}{8\pi} S(r) \right]^{\frac{1}{3}}$$

where 
$$S(r) = \frac{\sigma(r)}{4\pi r^2}, \quad \sigma(r) = \sum_{n,\ell} \omega_{n\ell} [P_{n\ell}(r)]^2$$

$\omega_{n\ell}$  = occupation number for the orbital  $(n, \ell)$   
 =  $2(2\ell + 1)$  for a closed shell

The total number of electrons is  $N = \sum_{n,\ell} \omega_{n\ell}$ , and the ionicity is  $Z - N$ .

The  $P_{n\ell}$ 's are normalized solutions of the radial Schroedinger equation:

$$\left\{ \frac{-d^2}{dr^2} + \frac{\ell(\ell+1)}{r^2} + V(r) \right\} P_{n\ell}(r) = E_{n\ell} P_{n\ell}(r)$$

i.e. 
$$P_{n\ell}(r) = r R_{n\ell}(r)$$

The ionicity parameters were chosen in accordance with the ordinary ideas of chemical valence (i.e. ionicity of  $Ag^+ = +1$ , ionicity of  $Cl^- =$  ionicity of  $Br^- = -1$ ).

The potentials within each sphere are modified by adding (or subtracting) the Madelung potential  $V_M = \pm \frac{2\alpha}{a/2} = \pm \frac{4\alpha}{a}$  where  $\alpha$  is the Madelung constant for an NaCl structure ( $\alpha = 1.747558$ ) and "a" is the cube edge (see Figure I-1). That is:

about silver sites 
$$V(r) = (V_{\text{Herman-Skillman}})_{Ag^+} + V_M$$
  
 about halogen sites 
$$V(r) = (V_{\text{Herman-Skillman}})_{\text{halogen}} - V_M$$

The choice of the sphere radii and the initial determination of  $V_0$  was made in the following way. First the Herman-Skillman ionic potentials for  $\text{Ag}^+$  and  $\text{Cl}^-$  were superimposed and plotted in the (100) direction (Figure I-2-a). Then these potentials were corrected by adding or subtracting the Madelung potential. The point where the Madelung corrected potentials cross defines the sphere radii and the first determination of  $V_0$  (Figure I-2-b). This scheme has the desirable effect of insuring that  $V(\vec{r})$  is continuous throughout the crystal. Finally we choose the zero of potential to be  $V_0$  on the APW scale. The net result of the Madelung correction and change of the zero of energy is that the Herman-Skillman potentials have been altered by different amounts called  $V_{\text{SHIFT}}$ .

$$\text{for } \text{Ag}^+ \quad V_{\text{SHIFT}} = V_0 + V_M$$

$$\text{for halogen} \quad V_{\text{SHIFT}} = V_0 - V_M$$

and our corrected potentials become:

$$\text{Ag}^+: \quad V(r) = (V_{\text{Herman-Skillman}})_{\text{Ag}^+} + (V_{\text{SHIFT}})_{\text{Ag}^+}$$

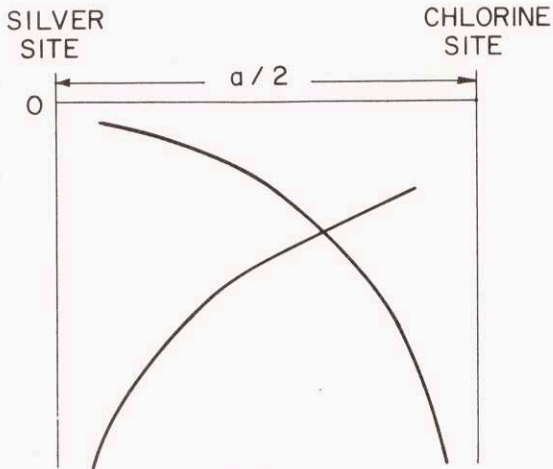

$$\text{halogen:} \quad V(r) = (V_{\text{Herman-Skillman}})_{\text{halogen}} + (V_{\text{SHIFT}})_{\text{halogen}}$$

This potential is shown in Figures I-2-c and I-2-d for the (100) and (110) directions.

(f)

Unfortunately, when the above scheme is used in determining the sphere radii and  $V_0$ , the bands subsequently found do not agree with experimental facts. Specifically, the band gap at  $\vec{k} = 0$  is too small for both AgCl and AgBr. This discrepancy may be resolved by varying the magnitude of  $V_0$  until agreement with experiment is obtained. For both AgCl and AgBr the experimental band gap at  $\vec{k} = 0$ ,  $E_g$ , was duplicated when the magnitude of  $V_0$  was reduced. This final potential is shown in Figures I-2-e and I-2-f for the (100) and (110) directions, respectively.

There are two reasons why this corrected potential should be more representative of the actual crystalline potential than that shown in Figures I-2-c and I-2-d. Along the line joining the APW sphere centers (x, y, or z directions) the ionic potentials employed will have some value  $V$  at the sphere radii. However, in some other direction the actual crystalline potential just beyond either of the APW spheres will not be equal to  $V$  as in Figure I-2-d, but will have some larger value as in our corrected potential (Figure I-2-f). Also, the valence p and d states as well as the core electrons should be fairly insensitive to the value of the potential between spheres.

Although the size of the band gap at  $\vec{k} = 0$  depends in a critical way on the value of the potential between spheres, the relative spacing of core states is almost independent of  $V_0$ . In fact, changing  $V_0$  by as much as a few tenths of a Rydberg only changed the relative spacings of valence bands by less than .01 Rydbergs, and left their

qualitative features virtually unchanged.

The Brillouin zone for the FCC lattice is shown in Figure I-3, and the APW bands for AgCl and AgBr are shown in Figures I-4 and I-5 respectively. Values for the sphere radii,  $V_0$ ,  $V_{\text{SHIFT}}$ ,  $V_M$ , the ionic potentials as functions of  $r$ , the starting values of the wave functions, and the points in the Brillouin zone actually calculated for the bands in Figures I-4 and I-5 are given in Appendix One.

At this point it should be mentioned that because our basis functions are located on different sites on the unit cell, the symmetry properties of certain eigenstates of the Hamiltonian depend on which ion is located at the origin of coordinates. Switendick<sup>5</sup> has shown that within the Brillouin zone it makes no difference which ion is at the origin; but on the surface of the Brillouin zone, the representation matrices for the ion located at  $\vec{R}_n = \frac{a}{2} (1,0,0)$  must be multiplied by the factor  $e^{i(\vec{R}\vec{K}_\ell - \vec{K}_\ell)\cdot\vec{R}_n}$  (here  $R$  is an operation of the group under consideration, and  $\vec{K}_\ell$  is a vector of the reciprocal lattice). One finds that the symmetries at L, W, and Q are affected. The results are shown below in Table 1-1.

center A at origin	center B at $\frac{a}{2} (010)$
L <sub>1</sub>	L <sub>2</sub>
L <sub>2</sub>	L <sub>1</sub>
L <sub>3</sub>	L <sub>3</sub>
L <sub>1</sub>	L <sub>2</sub>
L <sub>2</sub>	L <sub>1</sub>
L <sub>3</sub>	L <sub>3</sub>

Table I-1 (continued)

center A at origin	center B at $\frac{a}{2} (0,1,0)$
$W_1$	$W_2'$

$W_1'$	$W_2$
$W_2'$	$W_1$
$W_3$	$W_3$
$Q_+$	$Q_-$
$Q_-$	$Q_+$

After solving the secular equations and obtaining eigenvalues, the eigenfunctions may also be determined. For points of major interest in the Brillouin zone, we have obtained the radial charge densities,  $P_{\alpha\ell}^z(r)$ , within each APW sphere. The total amount of charge in each sphere associated with a given " $\ell$ " value,  $q_\ell$ , and the amount of plane-wave charge (between spheres) has been calculated and is also tabulated in Appendix One. Here the total amounts of charge are normalized to unity; i.e.

$$\sum_{\ell=0}^{L_{\max}=12} (q_\ell)_{\text{Ag}^+ \text{ sphere}} + \sum_{\ell=0}^{L_{\max}=12} (q_\ell)_{\text{Halogen sphere}} + \text{plane wave charge} = 1$$

However, in Appendix One these quantities are tabulated for only the first three  $\ell$  values ( $\ell = 0, \ell = 1, \ell = 2$ ).

Since the group of the wave vector at  $\vec{k} = 0$  (point group  $O_h$ ) contains the inversion, the bands are parity eigenstates at  $\Gamma$ . By examining the charge within each APW sphere (Appendix One) the valence bands at this point are seen to arise predominately from either p or

Figure I-3

BRILLOUIN ZONE FOR FCC LATTICE

Figure I-4

BAND STRUCTURE OF SILVER CHLORIDE

Figure I-5

BAND STRUCTURE OF SILVER BROMIDE

d functions with no mixing of p and d states. At  $\Gamma_{15}$  the eigenfunction is mostly  $\text{Cl}^-(3p)$  or  $\text{Br}^-(4p)$  with some  $\text{Ag}^+(5p)$ . The  $\Gamma_{12}$  and  $\Gamma_{25}$  states are almost entirely  $\text{Ag}^+(4d)$ .

As one departs from  $\Gamma$  along any of the three symmetry directions, the bands exhibit a strong p-d mixing.

In the (100) or  $\Delta$  direction, the p-d mixing is zero at  $\Gamma$ , increases until  $\vec{k} = \frac{\pi}{a}(1,0,0)$ , and then decreases to zero at the point X (the point group at X is  $D_{4h}$  and includes the inversion operation).

Along the (110) or  $\Sigma$  direction, the mixing is greatest at the point  $\vec{k} = \frac{\pi}{a}(1,1,0)$ . Because of transformation properties listed in Table 1-1, the  $\text{Ag}^+(4d)$  function located at the origin and the  $\text{Cl}^-(3p)$  (or  $\text{Br}^-(4p)$ ) function located at  $\frac{a}{2}(0,1,0)$  both have even parity at the point L. Consequently, this point is one of greatest p-d mixing along the (111) direction.

As one can see, a superficial understanding of the interactions away from  $\Gamma$  can be partially obtained from our APW calculation. However, because of the complexity of the details of an APW calculation it becomes increasingly more difficult to obtain additional information about these interactions. In order to better understand the nature of the bands, in Chapter II we illustrate a fitting procedure based on the use of tight binding wave functions. As we will see, the detailed nature of the various interactions involved become quite evident, even with a very crude fitting.

Before proceeding to Chapter II, we mention that when spin is

introduced in the Hamiltonian, direct optical transitions are allowed between all bands except at some points where the wave functions are parity eigenstates ( $\Gamma$ , X, and L); electric dipole transitions are allowed only between states of opposite parity. Also, indirect or phonon-assisted transitions from the uppermost valence bands to the conduction band are allowed. Details regarding both types of transition are given in Appendix Four.

Finally, we mention that the APW bands for AgCl and AgBr in figures I-4 and I-5 are approximately consistent with all experiments known to the author. A more detailed comparison of the bands and experimental results will be given in Chapter III.

## Chapter II

### Band Fitting by Tight Binding Method

#### II-1. Introduction

In this chapter we shall show how the APW bands calculated in Chapter I may be described by analytic functions with a parametric fit of the bands. This fitting technique has been described in detail by Slater and Koster.<sup>6</sup> In this method we begin with orthogonalized, Bloch-like, tight binding wave functions. The usual integrals of the Hamiltonian between Bloch functions are regarded as disposable constants used to fit the bands. These constants appear as the integral between functions on the same ionic site as well as first, second, and higher nearest neighbors. Naturally one can fit the APW bands to any desired accuracy if a complete set of basis functions is used and if one includes integrals involving functions on ions that are widely separated in the crystal.

The philosophy of the interpolation scheme employed here will not be that of obtaining an exact fit for all bands. But rather, we try to obtain a reasonable fitting for the upper valence bands using a restricted basis set (only functions of p and d symmetry), and including only as many interactions (i.e. disposable parameters) as necessary to approximate the APW bands. The value of fitting the bands in this way is that one can understand the basic structure of the APW bands without a great deal of numerical labor.

Since the bands for AgCl and AgBr have a very similar structure (see Figures I-4 and I-5), only the fitting of the AgCl bands will be described here. Fortunately, Slater and Koster have discussed the tight binding interpolation scheme extensively, and in the treatment of the AgCl fitting we will use the results of their work.

## II-2. AgCl fit.

One starts with a set of normalized basis functions  $\phi_1(\vec{r}), \dots, \phi_n(\vec{r})$  that are orthogonal even when the functions are located on different centers in the crystal. That is, if the vectors  $\vec{R}_\ell$  ( $\vec{R}_\ell = l_1\hat{i} + l_2\hat{j} + l_3\hat{k}$ ) denote ionic sites in the crystal, then

$$\int \phi_i^*(\vec{r}-\vec{R}_\ell) \phi_j(\vec{r}-\vec{R}_{\ell'}) dv = \delta_{ij} \delta_{\ell\ell'} \quad (\text{II-1})$$

From our functions  $\phi_i$ , we construct normalized Bloch functions

$$\psi_{i,k}(\vec{r}) = \frac{1}{\sqrt{N}} \sum_{\vec{R}_\ell} e^{i\vec{k}\cdot\vec{R}_\ell} \phi_i(\vec{r} - \vec{R}_\ell) \quad (\text{II-2})$$

(N = number of unit cells)

The wave function for an electron in the crystal is then written as

$$\Psi = \sum_{i=1}^n a_i \psi_i$$

and the  $n \times n$  secular equation is obtained in the usual way. The

matrix elements are

$$H_{ij}(\vec{k}) = \sum_{\vec{R}_\ell} e^{i\vec{k} \cdot \vec{R}_\ell} E_{ij}(\ell_1 \ell_2 \ell_3) \quad (\text{II-3})$$

where

$$E_{ij}(\ell_1 \ell_2 \ell_3) = \int \phi_i^*(\vec{r}) H \phi_j(\vec{r} - \ell_1 \hat{i} - \ell_2 \hat{j} - \ell_3 \hat{k}) dv \quad (\text{II-4})$$

For AgCl (with the silver ion located at the origin) we have silver ions at

$$\vec{R}_s = \frac{a}{2} (s_1 \hat{i} + s_2 \hat{j} + s_3 \hat{k}) \quad s_1 + s_2 + s_3 = \text{even integer}$$

and chlorine ions at

$$\vec{R}_c = \frac{a}{2} (c_1 \hat{i} + c_2 \hat{j} + c_3 \hat{k}) \quad c_1 + c_2 + c_3 = \text{odd integer}$$

Our basis functions are

$$\begin{aligned} \phi_1 &= f(r)xy && \text{five Ag}^+ \text{ 4d functions} \\ \phi_2 &= f(r)xz \\ \phi_3 &= f(r)yz && (\text{II-5}) \\ \phi_4 &= f(r) \sqrt{3}(x^2 - y^2) \\ \phi_5 &= f(r) (3z^2 - r^2) \end{aligned}$$

$$\begin{aligned} \phi_6 &= i g(r) x && \text{three Cl}^- \text{ 3p functions} \\ \phi_7 &= i g(r) y \\ \phi_8 &= i g(r) z \end{aligned}$$

and our Bloch functions  $\psi_i$  are

$$\psi_i = \begin{cases} \frac{1}{\sqrt{N}} \sum_{\vec{R}_s} e^{i\vec{k} \cdot \vec{R}_s} \phi_i(\vec{r} - \vec{R}_s) & i = 1, 2, 3, 4, 5 \\ \frac{1}{\sqrt{N}} \sum_{\vec{R}_c} e^{i\vec{k} \cdot \vec{R}_c} \phi_i(\vec{r} - \vec{R}_c) & i = 6, 7, 8 \end{cases} \quad (\text{II-6})$$

Thus our final matrix elements in equations II-3 and II-4 may be described as resulting from d-d interactions (both functions on silver sites), p-p interactions (both functions on chlorine sites), and p-d interactions (one function on a chlorine site, the other on a silver site).

Using the abbreviations  $\xi = \frac{k_x a}{2}$ ,  $\eta = \frac{k_y a}{2}$ ,  $\zeta = \frac{k_z a}{2}$  the matrix elements (equation II-3) as derived by Slater and Koster are given in Table II-1.\*

To start the fitting procedure, we begin with  $\vec{k}$  in the (001) direction since many of the matrix elements in Table II-1 vanish when  $\xi = \eta = 0$ . In addition, we observe that many matrix elements are identical to each other, and we obtain the Hamiltonian matrix:

---

\* Slater and Koster do not list all the matrix elements since many are related by cyclical permutations of coordinates.

Table II-1

d-d

$$\begin{aligned}
 H_{11} &= E_{11}(000) + 4E_{11}(110) \cos \xi \cos \eta + 4E_{11}(011) \cos \zeta (\cos \xi + \cos \eta) \\

 H_{35} &= 2E_{15}(110) \sin \eta \sin \zeta \\
 H_{45} &= \sqrt{3} E_{55}(110) \cos \zeta (\cos \xi - \cos \eta) - \sqrt{3} E_{44}(110) \cos \zeta (\cos \xi - \cos \eta)
 \end{aligned}$$

Table II-1 (continued)

p-d

$H_{61} = 2E_{61}(010)\sin\eta$	$H_{71} = 2E_{61}(010)\sin\xi$	$H_{81} = 0$
$H_{62} = 2E_{61}(010)\sin\zeta$	$H_{72} = 0$	$H_{82} = 2E_{61}(010)\sin\xi$
$H_{63} = 0$	$H_{73} = 2E_{61}(010)\sin\zeta$	$H_{83} = 2E_{61}(010)\sin\eta$
$H_{64} = \sqrt{3} E_{85}(001)\sin\xi$	$H_{74} = -\sqrt{3} E_{85}(001)\sin\eta$	$H_{84} = 0$
$H_{65} = -E_{85}(001)\sin\xi$	$H_{75} = -E_{85}(001)\sin\eta$	$H_{85} = 2E_{85}(001)\sin\zeta$

p-p

$$H_{66} = E_{66}(000) + 4E_{66}(110)\cos\xi(\cos\eta + \cos\zeta) + 4E_{66}(011)\cos\eta\cos\zeta$$

$$H_{77} = E_{66}(000) + 4E_{66}(110)\cos\eta(\cos\xi + \cos\zeta) + 4E_{66}(011)\cos\xi\cos\zeta$$

$$H_{88} = E_{66}(000) + 4E_{66}(110)\cos\zeta(\cos\eta + \cos\xi) + 4E_{66}(011)\cos\eta\cos\xi$$

$$H_{67} = -4E_{67}(110)\sin\xi\sin\eta$$

$$H_{68} = -4E_{67}(110)\sin\xi\sin\zeta$$

$$H_{78} = -4E_{67}(110)\sin\eta\sin\zeta$$

$$H(00\zeta) = \begin{pmatrix} H_{11} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & H_{22} & 0 & 0 & 0 & H_{62} & 0 & 0 \\ 0 & 0 & H_{22} & 0 & 0 & 0 & H_{62} & 0 \\ 0 & 0 & 0 & H_{44} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & H_{55} & 0 & 0 & H_{85} \\ 0 & H_{62} & 0 & 0 & 0 & H_{66} & 0 & 0 \\ 0 & 0 & H_{62} & 0 & 0 & 0 & H_{66} & 0 \\ 0 & 0 & 0 & 0 & H_{85} & 0 & 0 & H_{88} \end{pmatrix} \quad (\text{II-7})$$

By comparing our basis functions  $\phi_1, \dots, \phi_8$  with basis functions for the group of  $\Delta$  (group  $C_{4v}$ ) and observing that  $\Delta_5$  is a doubly degenerate state, we easily find the bands in the  $\Delta$  direction are given by

$$\Delta_2^1: \text{energy, } \epsilon = H_{11}(00\zeta)$$

$$\Delta_2: \quad \epsilon = H_{44}(00\zeta)$$

$$\Delta_1: \det \begin{pmatrix} H_{55}-\epsilon & H_{85} \\ H_{85} & H_{88}-\epsilon \end{pmatrix} = 0, \quad \epsilon = \frac{(H_{55}+H_{88})}{2} \pm \frac{H_{55}-H_{88}}{2} \sqrt{1 + \frac{4H_{85}^2}{(H_{55}-H_{88})^2}}$$

$$\Delta_5: \det \begin{pmatrix} H_{22}-\epsilon & H_{62} \\ H_{62} & H_{66}-\epsilon \end{pmatrix} = 0, \quad \begin{array}{l} \text{both roots occurring twice} \\ \epsilon = \frac{(H_{55}+H_{66})}{2} \pm \frac{H_{22}-H_{66}}{2} \sqrt{1 + \frac{4H_{62}^2}{(H_{22}-H_{66})^2}} \end{array}$$

where

$$H_{11}(00\zeta) = E_{11}(000) + 4E_{11}(110) + 8 E_{11}(011) \cos \zeta$$

$$H_{44}(00\zeta) = E_{55}(000) + 4E_{44}(110) + [6 E_{55}(110) + 2E_{44}(110)] \cos \zeta$$

$$H_{22}(00\zeta) = E_{11}(000) + 4E_{11}(110) \cos \zeta + 4E_{11}(011)(1 + \cos \zeta)$$

$$H_{55}(00\zeta) = E_{55}(000) + 4E_{55}(110) \left[1 + \frac{\zeta}{2} \cos \zeta\right] + 6E_{44}(110) \cos \zeta$$

$$H_{66}(00\zeta) = E_{66}(000) + 4E_{66}(110) (1 + \cos \zeta) + 4E_{66}(011) \cos \zeta$$

$$H_{88}(00\zeta) = E_{88}(000) + 8E_{66}(110) \cos \zeta + 4E_{66}(011)$$

$$H_{62}(00\zeta) = 2E_{62}(010) \sin \zeta$$

$$H_{85}(00\zeta) = 2E_{85}(001) \sin \zeta$$

The diagonal matrix elements are determined by fitting at  $\Gamma$  and X (where the off-diagonal elements vanish). Thus we determine the  $E_{ii}$ 's along the bands

$$\begin{aligned} \Gamma_{25}' &- \Delta_2 &- X_3 \\ \Gamma_{12}' &- \Delta_2 &- X_2 \\ \Gamma_{15}' &- \Delta_1 &- X_4' \\ \Gamma_{25}' &- \Delta_1 &- X_1 \\ \Gamma_{15}' &- \Delta_5 &- X_5' \\ \Gamma_{25}' &- \Delta_5 &- X_5 \end{aligned} \tag{II-8}$$

The fitting for  $\Delta_2'$  and  $\Delta_2$  turns out to be quite accurate. However, the fit for  $\Delta_1$  and  $\Delta_5$  at points between  $\Gamma$  and X is poor because the p-d matrix elements are non zero. In fact, the  $\Delta_1$  bands are not even fit properly at X; since without the p-d interaction we have bands  $\Gamma_{15}' - \Delta_1 - X_4'$  and  $\Gamma_{25}' - \Delta_1 - X_1$  whereas the APW bands are  $\Gamma_{15}' - \Delta_1 - X_1$  and  $\Gamma_{25}' - \Delta_1 - X_4'$ .

To include the p-d interaction, we fit at the point  $\vec{k} = \frac{\pi}{a} (001)$

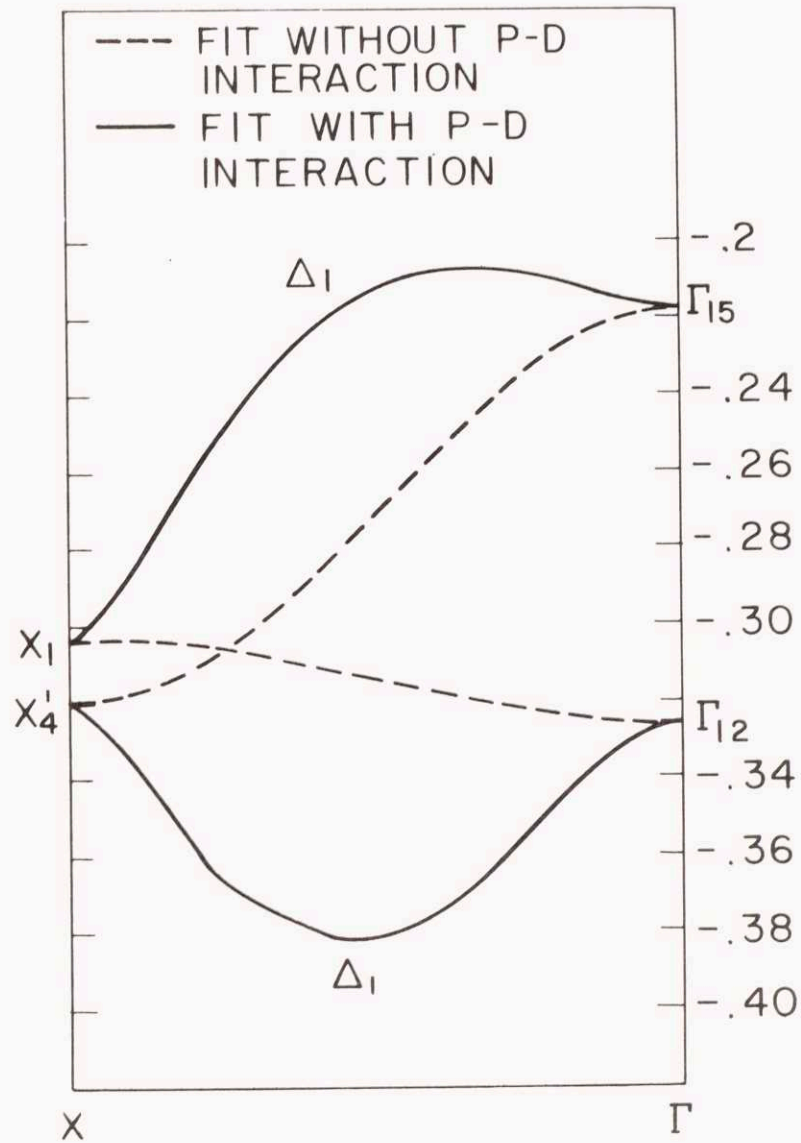

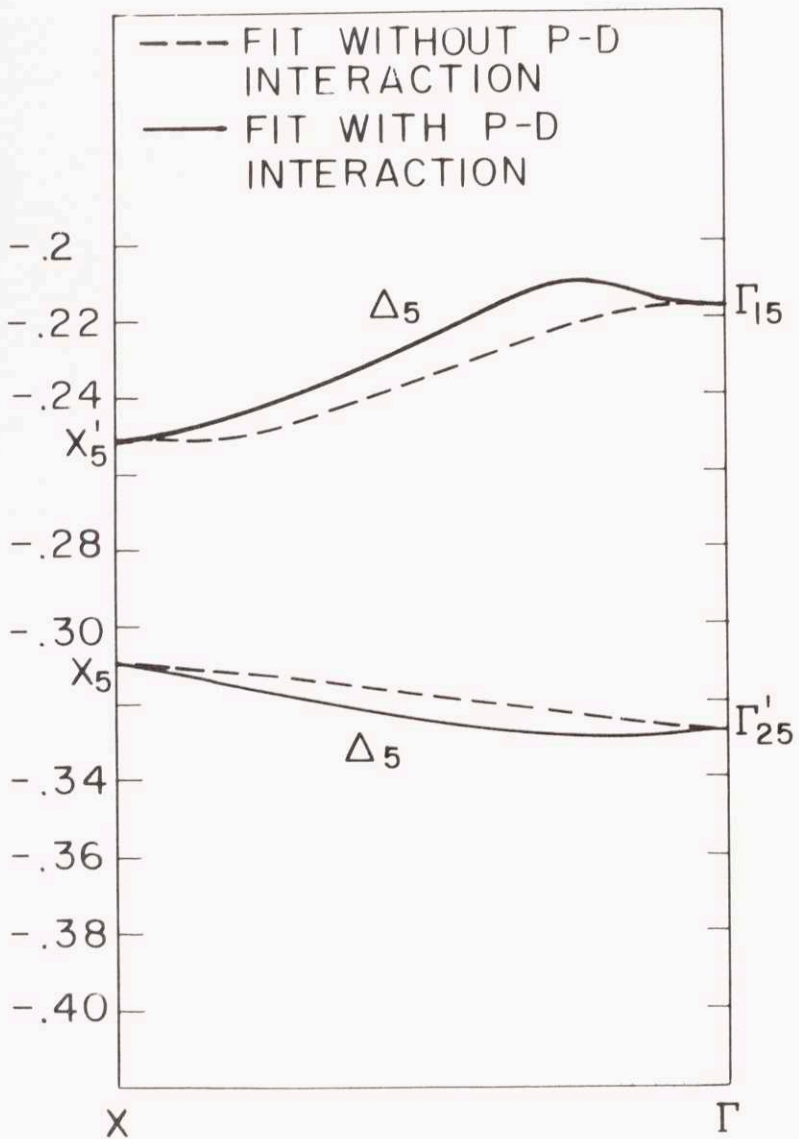

(or  $\zeta = \pi/2$ ) where the off diagonal elements  $H_{62}$  and  $H_{85}$  are largest. However, because our bands in reality cannot be exactly described only in terms of a p-d interaction, the values of the parameters  $E_{61}(010)$  and  $E_{85}(001)$  will depend on which  $\Delta_1$  or  $\Delta_5$  band we fit. More precisely to fit along  $\Gamma'_{25} - \Delta_5 - X_5$  we obtain  $E_{61}(010) = .0133765$ ; along  $\Gamma'_{15} - \Delta_5 - X'_5$ ,  $E_{61}(010) = .0149219$ . Similarly along  $\Gamma'_{12} - \Delta_1 - X'_4$  and  $\Gamma'_{15} - \Delta_1 - X_1$  we obtain  $E_{85}(001)$  equal to .041647 and .0385722 respectively. In Figures II-1 and II-2 we illustrate these fitted bands with and without the p-d interaction. For an "overall fit" the average values of  $E_{61}(010)_{\text{avg}} = .014092$  and  $E_{85}(001)_{\text{average}} = .0401096$ .

In the (110) or  $\Sigma$  direction ( $\xi = \eta$ ,  $\zeta = 0$ ) the Hamiltonian matrix is:

$$H(\xi, \xi, 0) = \begin{bmatrix} H_{11} & 0 & 0 & 0 & H_{15} & H_{61} & H_{61} & 0 \\ 0 & H_{22} & H_{23} & 0 & 0 & 0 & 0 & H_{61} \\ 0 & H_{23} & H_{22} & 0 & 0 & 0 & 0 & H_{61} \\ 0 & 0 & 0 & H_{44} & 0 & H_{65} & H_{65} & 0 \\ H_{15} & 0 & 0 & 0 & H_{55} & H_{65} & H_{65} & 0 \\ H_{61} & 0 & 0 & H_{65} & H_{65} & H_{66} & H_{67} & 0 \\ H_{61} & 0 & 0 & H_{65} & H_{65} & H_{67} & H_{66} & 0 \\ 0 & H_{61} & H_{61} & 0 & 0 & 0 & 0 & H_{88} \end{bmatrix} \quad (\text{II-9})$$

By direct substitution, one may verify that eigenvectors of the matrix II-9 are:

Figure II-1 FITTING BINDING FIT OF THE BANDS  $\Gamma_{15-\Delta_5-X'_5}$  AND  $\Gamma'_{25-\Delta_5-X_5}$   
Figure II-2 FITTING BINDING FIT OF THE BANDS  $\Gamma_{15-\Delta_1-X_1}$  AND  $\Gamma'_{12-\Delta_1-X'_4}$

$$\begin{array}{cccc}
 v_1 = \begin{bmatrix} v_{11} \\ 0 \\ 0 \\ 0 \\ v_{15} \\ v_{16} \\ v_{16} \\ 0 \end{bmatrix} & 
 v_2 = \begin{bmatrix} 0 \\ v_{22} \\ -v_{22} \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} & 
 v_3 = \begin{bmatrix} 0 \\ v_{32} \\ v_{32} \\ 0 \\ 0 \\ 0 \\ 0 \\ v_{38} \end{bmatrix} & 
 v_4 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ v_{44} \\ 0 \\ v_{46} \\ -v_{46} \\ 0 \end{bmatrix} & 
 \text{(II-10)}
 \end{array}$$

i.e.  $Hv_i = \epsilon_i v_i$

Comparing these eigenvectors with basis functions for the group of  $\Sigma$  (group  $C_{3v}$ ), we find that the eigenvector  $v_1$  corresponds to the irreducible representation  $\Sigma_1$ . Since there are three independent coefficients for vector  $v_1$ , we will have three distinct eigenvalues corresponding to symmetry  $\Sigma_1$ . Similarly, we have one  $\Sigma_2$  band, two  $\Sigma_3$  bands, and two  $\Sigma_4$  bands arising from our  $Cl^-(3p)$  and  $Ag^+(4d)$  functions.

The corresponding secular equations are:

for  $\Sigma_1$  bands:

$$\det \begin{bmatrix} H_{11}-\epsilon & H_{15} & 2H_{61} \\ H_{15} & H_{55}-\epsilon & 2H_{65} \\ 2H_{61} & 2H_{65} & 2(H_{66}+H_{77}-\epsilon) \end{bmatrix} = 0 \quad \text{(II-11-a)}$$

for  $\Sigma_2$ :  $\epsilon = H_{22}-H_{23}$  (II-11-b)

$$\text{for } \Sigma_3: \quad \det \begin{bmatrix} 2(H_{22}+H_{23}-\epsilon) & 2H_{61} \\ 2H_{61} & H_{88}-\epsilon \end{bmatrix} = 0 \quad (\text{II-11-c})$$

$$\text{for } \Sigma_4: \quad \det \begin{bmatrix} H_{44}-\epsilon & -2 \ 3H_{65} \\ -2 \ 3H_{65} & 2(H_{66}-H_{67}-\epsilon) \end{bmatrix} = 0 \quad (\text{II-11-d})$$

In the  $\Sigma$  direction we again determine the off diagonal matrix elements where the p-d interaction is largest, i.e. at  $\zeta = \pi/2$  or  $k = \pi/a(1,1,0)$ . The matrix element  $H_{23} = -4E_{12}(011)$  can be found from a fit of the band  $\Gamma'_{25} - \Sigma_2 - K_2$  (equation II-11-b) or by fitting either of the  $\Sigma_3$  bands,  $\Gamma'_{15} - \Sigma_3 - K_3$  or  $\Gamma'_{25} - \Sigma_3 - K_3$ . However, we again encounter the same problems found in fitting the  $\Delta$  direction; namely that the three  $\Sigma$  bands cannot all be fit with any single value of  $E_{12}(011)$ . For simplicity, we determine  $E_{12}(011)$  along the  $\Gamma'_{25} - \Sigma_2 - K_2$  band, and obtain  $E_{12}(011) = .0009562$ .

The matrix element  $H_{67} = -4E_{67}(011)$  is determined by fitting either of the  $\Sigma_4$  bands  $\Gamma'_{15} - \Sigma_4 - K_4$  or  $\Gamma'_{12} - \Sigma_4 - K_4$ . Once more, a single value of  $E_{67}(011)$  will not fit both bands. Since the  $\Sigma_4$  band arising from  $\Gamma'_{15}$  is the highest in the valence band (note: when relativistic effects and other perturbations are included, the  $L_3$  state will lie slightly higher), we fit along  $\Gamma'_{15} - \Sigma_4 - K_4$  at the point  $\vec{k} = \frac{\pi}{a}(1,1,0)$  or  $\eta = \pi/2$ . From equation II-11-d we obtain  $E_{67}(011) = .0205815$ .

In a similar manner we determine  $H_{15} = -4E_{15}(110)$  from any one

of the three  $\Sigma_1$  bands. As in our previous calculations, a fitting along these three bands cannot be accomplished with any single value of  $E_{15}(110)$ . The average value is  $E_{15}(110)_{\text{average}} = .0109872$ .

Our fitting in the  $\Delta$  and  $\Sigma$  directions has determined all matrix elements up to nearest neighbor interactions. To this extent we have also determined the bands in the (111) direction. A summary of the parameters is given in Table II-2, and in Table II-3 we compare the APW and fitted valence bands for the  $\Delta$ ,  $\Lambda$ , and  $\Sigma$  directions.

	$L_3$	-.3137	-.2759

As Table II-3 indicates, our simplified fitting is not too bad quantitatively, especially for the higher valence bands. For this reason we may conclude that this higher band may be understood on the basis of a single  $p$ - $d$  interaction. However, since the greatest discrepancies are found at the bottom of the "d" bands (especially along the  $\Gamma_{12} - \Sigma_4 - K_4$  and  $\Gamma_{12} - \Lambda_1 - L_1$  bands), we may safely conclude that a good fitting here would necessitate the use of additional core wave functions in the basis set.

### Chapter III

#### Calculation of Perturbation Effects

##### III-1. Introduction.

In considering the effects of perturbations on our APW bands, we will be primarily concerned with the states  $\Gamma_{15}$  and  $L_3$  at the top of the valence band. The reason for focusing our attention on these states is that two important experimentally obtained results are the magnitudes of the direct band gap at  $\vec{k} = 0$ ,  $E_g$ , and the indirect band gap,  $E_{ig}$ . The value for  $E_g$  is given by the difference of the energies of the  $\Gamma_1$  (conduction band) and  $\Gamma_{15}$  states. The indirect gap is the difference of the energies of the  $\Gamma_1$  state and the highest valence band state, where ever that may be. The experimental values for these quantities are:<sup>7,8</sup>

	$E_{ig}$	$E_g$
AgCl	3.25 ev	5.13 ev
AgBr	2.68 ev	4.29 ev

There may be some question about whether or not these values correspond exactly to transitions between electronic bands or from an electronic valence band to an exciton band at  $\Gamma_1$ . However, for the purposes of the present discussion we need not be concerned with this detail. The important point is that the APW bands given in Chapter I were fit so that the APW value for  $E_g$  would agree with experiment. Unfortunately, even after fitting the APW bands to agree with  $E_g$ , the APW

values for  $E_{ig}$  are:

$$\text{for AgCl} \quad E_{ig} = 3.84 \text{ ev.}$$

$$\text{for AgBr} \quad E_{ig} = 3.24 \text{ ev.}$$

Thus, for both crystals the calculated value of the indirect band gap is too large by approximately .5 ev.

It turns out that after considering some of the deviations of the APW potential used from the actual crystalline potential, the discrepancy in  $E_{ig}$  can be resolved. But before discussing the various perturbations, we first return to the definitions of the two band gaps. In the early APW calculations the value of  $V_0$  was set so that the difference of the  $\Gamma_1$  and  $\Gamma_{15}$  states equalled  $E_g$ . Unfortunately, this straightforward definition will lead to confusion when we consider spin-orbit coupling which splits the  $\Gamma_{15}$  state, so we redefine  $E_g$  as follows:

$$E_g = \text{energy difference of lowest conduction band and highest valence band at } \vec{k} = 0.$$

Similarly,

$$E_{ig} = \text{energy difference of lowest conduction band and highest valence band state.}$$

Since the original APW bands were calculated on the basis of fitting  $E_g$ , we continue to let  $E_g$  be fit even after the perturbations have been applied. This can be done in effect by ignoring the conduction band entirely and studying the difference of the highest valence

band state and the highest valence band state at  $\vec{k} = 0$ . Let us call this difference  $\Delta$ .

Thus for our APW calculations, the quantity  $\Delta = E_g - E_{ig}$  is too small for both AgCl and AgBr.

The perturbations that we will study are the effect of the cubic field inside an APW sphere, and relativistic effects - the mass velocity shift and spin-orbit coupling.

Calculations will be made by first-order perturbation theory. Second order contributions are small (and will be neglected) because the states of interest are widely separated in energy from any states of like symmetry.

### III-2. Cubic field perturbation.

Since the APW method assumes a spherically symmetric potential inside each sphere, any effects of the actual cubic field potential enter the APW calculation only through the constant potential in the region between spheres. Thus, the APW cubic field splittings are necessarily smaller than the correct splittings; and in this section we will study the effect of the non-spherical cubic field inside spheres.

About an ionic site the cubic field may be written as

$$V(\vec{r}) = \pm \left\{ \frac{2\alpha}{a/2} + (3.58) \frac{2a_0}{a/2} \left( \frac{r}{a/2} \right)^4 \left( -\frac{3}{2} + \frac{5}{2} \frac{x^4+y^4+z^4}{r^4} \right) + \text{terms involving higher powers of } r \right\}$$

where  $\alpha$  = Madelung constant for  $r < a/2$   
 $a_0$  = Bohr radius  
 + sign about silver sites  
 - sign about chlorine sites

(III-1)

The constant Madelung potential,  $\frac{2\alpha}{a/2}$ , has already been included in the APW calculation. We now consider the second and higher terms.

The cubic field will affect  $\underline{d}$  functions (only through the second term in III-1) but leave p like functions unchanged. Therefore, the  $\Gamma_{15}$  state (p like) will not be affected by the cubic field, but at the point  $L_3$  (containing a large amount of  $\underline{d}$  in the wave function) the cubic field will shift our APW bands. Thus, we must consider only the term  $V' = (2)(3.58)\left(\frac{a_0}{a/2}\right)\left(\frac{r}{a/2}\right)^4\left(-\frac{3}{2} + \frac{5}{2}\frac{x^4+y^4+z^4}{r^4}\right)$  and its effect on the  $\underline{d}$  like portion of the wave function at  $\Sigma_4$  and  $L_3$ .

For a given point  $\vec{k}$  in the Brillouin zone we have  $n$  orthogonal functions  $\phi_{\vec{k}}^{(1)}(\vec{r}), \dots, \phi_{\vec{k}}^{(n)}(\vec{r})$  ( $n =$  degeneracy of the band) which are eigenfunctions of the unperturbed APW Hamiltonian,  $H_0$ . These functions have the form

$$\phi_{\vec{k}}^{(i)}(\vec{r}) = \frac{1}{\sqrt{Q(\vec{k})}} \left\{ \begin{array}{l} e^{i\vec{k}\cdot\vec{R}_c} \sum_{\ell=0}^{L_{\max}} \sum_{m=-\ell}^{\ell} C_{\ell m}^{(i)}(\vec{k}) \frac{U_{\ell c}(r_c)}{U_{\ell c}(R_{sc})} Y_{\ell m}(\theta_i, \phi_c) \quad \text{within chlorine spheres} \\ e^{i\vec{k}\cdot\vec{R}_s} \sum_{\ell=0}^{L_{\max}} \sum_{m=-\ell}^{\ell} S_{\ell m}^{(i)}(\vec{k}) \frac{U_{\ell s}(r_s)}{U_{\ell s}(R_{ss})} Y_{\ell m}(\theta_s, \phi_s) \quad \text{within silver spheres} \\ \text{plane wave outside spheres} \end{array} \right. \quad \text{(III-2)}$$

where  $\vec{R}_c$  = chlorine ionic site  
 $\vec{R}_s$  = silver ionic site  
 $\vec{r}_c = \vec{r} - \vec{R}_c, \vec{r}_s = \vec{r} - \vec{R}_s, r_c = |\vec{r}_c|, r_s = |\vec{r}_s|$

$(\theta_c, \phi_c)$  are spherical angles about center  $\vec{R}_c$

$(\theta_s, \phi_s)$  are spherical angles about center  $\vec{R}_s$

$C_{\ell m}^{(i)}(\vec{k})$  and  $S_{\ell m}^{(i)}(\vec{k})$  are the coefficients of chlorine and silver respectively for the spherical harmonics in the  $i^{\text{th}}$  function tabulated in Appendix Two .

$\frac{U_{\ell c}(r_c)}{r_c} =$  chlorine radial wave function for a given  $\underline{\ell}$  value

$\frac{U_{\ell c}(R_{sc})}{R_{sc}} =$  chlorine radial wave function for a given  $\underline{\ell}$  value evaluated at the chlorine sphere radius.

$\frac{U_{\ell s}(r_s)}{r_s} =$  silver radial wave function for a given  $\underline{\ell}$  value

$\frac{U_{\ell s}(R_{ss})}{R_{ss}} =$  silver radial wave function for a given  $\underline{\ell}$  value evaluated at the silver sphere radius

$Q(\vec{k})$  is a normalization constant and is independent of  $i$ .

We will also need the quantities

$$q_{\ell c}(\vec{k}) = \frac{1}{Q(\vec{k})} \sum_{m=-\ell}^{\ell} |C_{\ell m}^{(i)}(\vec{k})|^2 = \frac{\int_0^{R_{sc}} U_{\ell c}^2(r_c) dr_c}{U_{\ell c}^2(R_{sc})} \quad (\text{III-3})$$

and

$$q_{\ell s}(\vec{k}) = \frac{1}{Q(\vec{k})} \sum_{m=-\ell}^{\ell} |S_{\ell m}^{(i)}(\vec{k})|^2 = \frac{\int_0^{R_{ss}} U_{\ell s}(r_s) dr_s}{U_{\ell s}^2(R_{ss})}$$

which are the amounts of charge (normalized to unity) associated with a particular  $\underline{\ell}$  value within the chlorine and silver spheres respectively.

Note that the  $q'_2$ 's are independent of  $\underline{i}$ .

The above notation is written for AgCl. For AgBr, simply replace the letter  $\underline{C}$  by the letter  $\underline{B}$  everywhere.

The first order energy shift due to the cubic field perturbation for the  $L_3$  state is given by

$$\Delta E(\vec{k}) = \int_0^{R_s} \phi_{\vec{k}}^{*(i)}(\vec{r}_s) V'(\vec{r}_s) \phi_{\vec{k}}^{(i)}(\vec{r}_s) dv_s \quad (\text{III-4})$$

where we must integrate over the silver sphere, and the integral is independent of  $\underline{i}$ .

$$\text{Let } V'(\vec{r}_s) = \eta(r_s) V(\theta_s, \phi_s) \quad (\text{III-5})$$

$$\text{where } \eta(r_s) = (3.58) \frac{2a_0}{a/2} \left( \frac{r_s}{a/2} \right)^4$$

$$\text{and } V(\theta_s, \phi_s) = 1.5 [\sin^2 \theta_s \cos^2 \theta_s + \sin^4 \theta_s \sin^2 \phi_s \cos^2 \phi_s]$$

then after substituting equations III-2, III-3, and III-5 into III-4 we obtain

$$\Delta E(\vec{k}) = \frac{q_{2s}}{\sum_{m=-2}^2 |S_{2m}^{(1)}(\vec{k})|^2} \left\{ \int \left( \sum_{m=-2}^2 S_{2m}^{*(1)}(\vec{k}) Y_{2m}^*(\theta_s, \phi_s) \right) V(\theta_s, \phi_s) \left( \sum_{m=-2}^2 S_{2m}^{(1)}(\vec{k}) Y_{2m}(\theta_s, \phi_s) \right) d\Omega_s \right. \\ \left. \times \frac{\int_0^{R_{ss}} U_{2s}^2(r) \eta(r_s) dr_s}{\int_0^{R_{ss}} U_{2s}^2(r_s) dr_s} \right\} \quad (\text{III-6})$$

and finally

$$\Delta E(\vec{k}) = q_{2s} \frac{[ \frac{12}{21} (S_{22}^{(1)}(\vec{k}))^2 - \frac{16}{21} (R_e S_{21}^{(1)}(\vec{k}))^2 ]}{\sum_{m=-2}^2 |S_{2m}^{(1)}(\vec{k})|^2} \times 3.58 \frac{a_0}{a/2} < \left( \frac{r_s}{a/2} \right)^4 >$$

(III-7)

here  $R_e S_{21}^{(1)}(\vec{k}) = \text{Real part of } S_{21}^{(1)}(\vec{k})$

and  $< \left( \frac{r_s}{a/2} \right)^4 > = \text{average value of } \left( \frac{r_s}{a/2} \right)^4 \text{ within silver sphere}$

$$= \frac{\int_0^{R_{ss}} U_{2s}^2(r_s) \left( \frac{r_s}{a/2} \right)^4 dr_s}{\int_0^{R_{ss}} U_{2s}^2(r_s) dr_s}$$

After substituting the values of  $q_{2s}$  (given in Appendix One), the values of the  $S_{2m}^{(1)}$ 's (given in Appendix Two), and performing the radial integrations we obtain the cubic field shifts given in Table III-1.

Table III-1

	AgCl	AgBr	
$\Delta E =$	.00576	.00337	at $L_3$

Note that the additional cubic field within the APW spheres has the effect of raising the  $L_3$  state, or, equivalently, increasing  $\Delta = E_g - E_{ig}$ . The effect is smaller in AgBr because the lattice constant is larger (i.e., the strength of the cubic field is smaller in AgBr).

III-3. Mass-velocity perturbation.

The mass-velocity perturbation may be approximated by a spherically symmetric operator about each site in the crystal. Since the electron's speed is largest for core states and smallest far from ionic sites, we ignore the mass-velocity effect for the plane waves between APW spheres, and restrict ourselves to calculating the first order correction to a given energy level by considering only the portion of the wave function within spheres.

Because the mass-velocity perturbation,  $V'$ , is spherically symmetric about a given site, when the integral of  $V'$  between the APW functions (given in III-2) is calculated, all cross product terms of different  $\underline{\ell}$  and  $\underline{m}$  values vanish (because of the orthogonality of the spherical harmonics) and one finally obtains

$$\Delta E_{\text{mass-vel.}}(\vec{k}) = \sum_{\ell=0}^{L, \text{ max} = 12} \left( (q_{\ell c}(\vec{k})v_{\ell c} + q_{\ell s}(\vec{k})v_{\ell s}) \right) \quad (\text{III-8})$$

where the  $v$ 's are the ionic mass-velocity parameters defined by

$$v_{lc} = \frac{\int_0^{R_{sc}} U_{lc}^2(r_c) V'(r_c) dr_c}{\int_0^{R_{ss}} U_{lc}^2(r_c) dr_c} \quad (\text{III-9})$$

$$v_{ls} = \frac{\int_0^{R_{ss}} U_{ls}^2 r_s V'(r_s) dr_s}{\int_0^{R_{ss}} U_{ls}^2(r_s) dr_s}$$

We must now determine the mass-velocity parameters given in equations III-9. For a first estimate we can use the free-ion parameter since the radial wave functions within APW spheres for the free ions and the crystal are substantially the same, especially near the nucleus where the mass-velocity effect is largest.

For the free ions, Herman and Skillman calculated the mass-velocity shift by first order perturbation theory, averaging the mass-velocity operator  $V = -\alpha^2(E - V)^2$  over the free-ion wave function. However, a more accurate calculation has been performed by Waber<sup>9</sup> who solved the Dirac equation for the energies of the two possible  $j$  values of a given electron. By taking the appropriate weighted average of Waber's two eigenvalues, one obtains the energy for an electron with all relativistic effects included with the exception of spin-orbit coupling.

In Table III-2 below we compare the Herman-Skillman and Waber calculations for  $\text{Cl}^-(3p)$ ,  $\text{Br}^-(4p)$ , and  $\text{Ag}^+(4d)$  ionic eigenvalues.

Table III-2

	H-S (non-relativistic)	H-S(including mass-vel.)	Waber(rel)	Waber - H-S (mass-vel.)
Cl <sup>-</sup> (3p)	- .19094587	- .19794587	- .1906440	+ .00030187
Br <sup>-</sup> (4p)	- .18183391	- .21283391	- .1807204	+ .00104187
Ag <sup>+</sup> (4d)	-1.5682048	-1.6152048	-1.5082592	+ .0599456

(Note: the Herman-Skillman mass-velocity energy was found by interpolation from their tables which list only even Z energies).

Waber's eigenvalues are higher than those of Herman-Skillman for every case shown. This may be explained by the fact that the mass-velocity operator in reality produces two effects for a valence electron:

1. It lowers the eigenvalue because the mass-velocity operator is always negative.
2. It raises the eigenvalue because the core electrons are drawn closer to the nucleus, producing a stronger inner shielding of the nucleus.

The Herman-Skillman calculation ignores the second effect which, as Waber's calculation indicates, is actually greater in magnitude than the first.

It is interesting to note that Waber's eigenvalues are very

close to the Herman-Skillman non-relativistic energies. Therefore, in our perturbation calculation, we may approximate the mass-velocity parameter (to be substituted into equation III-8) by the difference of the Waber and Herman-Skillman (non-relativistic) levels given in column four of Table III-2. Thus,

$$\begin{aligned}
 \text{for } \text{Cl}^-(3p) \quad v_{1C} &= .00030 \\
 \text{for } \text{Br}^-(4p) \quad v_{1B} &= .00104 \\
 \text{for } \text{Ag}^+(4d) \quad v_{2S} &= .05995
 \end{aligned}
 \tag{III-10}$$

After substituting the mass-velocity parameter (equation III-10) and the appropriate  $q_l$ 's into equation III-8, we obtain the shifts in the bands at  $\Gamma_{15}$  and  $L_3$ . The results are given in Table III-3.

Table III-3  
Mass-velocity Shifts

	$\Gamma_{15}$	$L_3$
AgCl	.0002	.0399
AgBr	.0009	.0269

#### III-4. Spin-orbit coupling.

In this section we will calculate spin-orbit effects at our main points of interest, namely  $\Gamma_{15}$  and  $L_3$  at the top of the valence band. Since the spin-orbit parameters for the mixture of ionic states that we are concerned with (i.e.  $\text{Cl}^-(3p)$ ,  $\text{Br}^-(4p)$ ,  $\text{Ag}^+(4d)$  and  $\text{Ag}^+(5p)$ ) all are very small compared to the crystal field splitting (at  $\Gamma_{15}$  and  $L_3$ ), we may expect that a perturbation treatment of spin-orbit

coupling will be valid.

To compute spin-orbit energies, we must add spin to our original spin independent functions  $(\phi_{\vec{k}}^{(1)}(\vec{r}), \dots, \phi_{\vec{k}}^{(n)}(\vec{r}))$  given in equation III-2.

$$\text{Let } \psi_{\vec{k}}^{(1)}(\vec{r}) = \phi_{\vec{k}}^{(1)}(\vec{r})\alpha, \psi_{\vec{k}}^{(2)}(\vec{r}) = \phi_{\vec{k}}^{(2)}(\vec{r})\alpha, \dots, \psi_{\vec{k}}^{(n)}(\vec{r}) = \phi_{\vec{k}}^{(n)}(\vec{r})\alpha$$

$$\psi_{\vec{k}}^{(n+1)}(\vec{r}) = \phi_{\vec{k}}^{(1)}(\vec{r})\beta, \dots \qquad \psi_{\vec{k}}^{(2n)}(\vec{r}) = \phi_{\vec{k}}^{(n)}(\vec{r})\beta \qquad \text{(III-11)}$$

( $\alpha$  and  $\beta$  are the usual spinors, i.e.  $\alpha = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$   $\beta = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$ )

These  $2n$  functions form a basis for a  $2n$  dimensional representation of the double group at the point  $\vec{k}$ . In general, this  $2n$  dimensional representation will be reducible and may be decomposed into a sum of irreducible representations of the double group. In Appendix Four we give a brief discussion of the irreducible representations of the double group for the valence bands in AgCl and AgBr. A schematic drawing of these bands with spin included is shown in figure A4-1.

The spin-orbit operator is

$$H_{SO} = \xi(r) \vec{l} \cdot \vec{\sigma} \qquad \text{(III-12)}$$

where  $\xi(r) = \frac{\alpha^2}{2} \frac{1}{r} \frac{dV}{dr}$

$\alpha$  = fine structure constant

and  $\vec{l} \cdot \vec{\sigma} = l_x \sigma_x + l_y \sigma_y + l_z \sigma_z$

$$= \begin{bmatrix} l_z & l_- \\ l_+ & -l_z \end{bmatrix}$$

( $l_+$  and  $l_-$  are the usual raising and lowering operators)

When we calculate matrix elements of the spin-orbit operator between our  $2n$  functions  $\psi_{\vec{k}}^{(i)}(\vec{r})$  (equation III-11) we first note that all diagonal elements vanish (i.e.  $(H_{so})_{ii} = 0$ ). The reason for this is that the wave functions  $\psi_{\vec{k}}^{(i)}(\vec{r})$  are simple products of a Bloch orbital function times a spinor. Consequently, the matrix element

$$(H_{so})_{ii} = \langle \psi_{\vec{k}}^{(i)}(\vec{r}) | H_{so} | \psi_{\vec{k}}^{(i)}(\vec{r}) \rangle$$

where

$$= \sum_{j=x,y,z} [ \langle \phi_{\vec{k}}^{(i)}(\vec{r}) | \xi(\vec{r}) l_j | \phi_{\vec{k}}^{(i)}(\vec{r}) \rangle \langle s_i | \sigma_j | s_i \rangle ]$$

$$s_i = \begin{cases} \alpha & i=1, n \\ \beta & i = n+1, 2n \end{cases}$$

is a sum of three terms, each of which factors into a product of the matrix element of a component of the orbital angular momentum between Bloch functions (modified only by a radial operator), and a matrix element of the same component of the spin angular momentum between spinors.

Since the crystal Hamiltonian is invariant under inversion, we have

$$\phi_{\vec{k}}^{*(i)}(\vec{r}) = \phi_{-\vec{k}}^{(i)}(\vec{r}) = \phi_{\vec{k}}^{(i)}(-\vec{r}).$$

Using the fact that  $l_j = (-i\vec{r} \times \vec{\nabla})_j$ , the matrix element is:

$$\begin{aligned} \langle \phi_{\vec{k}}^{(i)}(\vec{r}) | \xi(\vec{r}) l_j | \phi_{\vec{k}}^{(i)}(\vec{r}) \rangle &= \int \phi_{\vec{k}}^{*(i)}(\vec{r}) [\xi(\vec{r}) l_j] \phi_{\vec{k}}^{(i)}(\vec{r}) dv \\ &= \int \phi_{-\vec{k}}^{(i)}(\vec{r}) [\xi(\vec{r}) l_j] \phi_{-\vec{k}}^{(i)*}(\vec{r}) dv \\ &= \int \phi_{\vec{k}}^{(i)}(\vec{r}) [\xi(\vec{r}) l_j] \phi_{\vec{k}}^{(i)*}(\vec{r}) dv \end{aligned}$$

$$\begin{aligned}
 &= - \int \phi_{\vec{k}}^{(i)}(\vec{r}) [\xi(r) l_j] \phi_{\vec{k}}^{(i)*}(\vec{r}) d\vec{v} \\
 &= - \langle \phi_{\vec{k}}^{(i)}(\vec{r}) | \xi(r) l_j | \phi_{\vec{k}}^{(i)}(\vec{r}) \rangle^*
 \end{aligned}$$

But this matrix element must be real; hence it is zero.

The fact that the first order matrix elements vanish has important consequences as far as the spin-orbit bands are concerned. Specifically, a band that is non degenerate without spin will be shifted only in second order by an amount proportional to  $\lambda^2/\Delta E$  where  $\lambda$  is of the order of the spin orbit parameters, and  $\Delta E$  the difference in energy of a neighboring band of similar symmetry (under the double group). Thus for the  $\Sigma_4$  band at the top of the valence band (labeled  $\Sigma_5$  in the double group), the shift is of order  $\lambda^2/\Delta E$  which is definitely negligible. Consequently, we must calculate only the splittings at  $\Gamma_{15}$  and  $L_3$  since these states are degenerate without spin.

The non-diagonal matrix elements of the spin-orbit operator are:

for  $i \neq j$

$$\begin{aligned}
 (H_{so})_{ij} &= \langle \psi_{\vec{k}}^{(i)}(\vec{r}) | H_{so} | \psi_{\vec{k}}^{(j)}(\vec{r}) \rangle \\
 &= \sum_{n,\ell} \sum_{m=-\ell}^{\ell} \sum_{m'=-\ell}^{\ell} \frac{C_{\ell m}^{*(i)}(\vec{k}) C_{\ell m'}^{(j)}(\vec{k})}{|C_{\ell m}^{(i)}(\vec{k})|^2} q_{\ell c}(\vec{k}) \xi_{n\ell}^{(c)}(\vec{\ell} \cdot \vec{\sigma})_{\ell m, \ell m'}^{ij}
 \end{aligned}$$

(III-13)

$$+ \sum_{n,\ell} \sum_{m=-\ell}^{\ell} \sum_{m'=-\ell}^{\ell} \frac{S_{\ell m}^{*(i)}(\vec{k}) S_{\ell m'}^{(j)}(\vec{k})}{|S_{\ell m}^{(i)}(\vec{k})|^2} q_{\ell s}(\vec{k}) \xi_{n\ell}^{(s)}(\vec{\ell} \cdot \vec{\sigma})_{\ell m, \ell m'}^{ij}$$

where  $(\vec{l} \cdot \vec{\sigma})_{\ell m, \ell m'}^{ij} = \langle Y_{\ell m} s_i | \vec{l} \cdot \vec{\sigma} | Y_{\ell m} s_j \rangle$

$$\zeta_{n\ell}^{(c)} = \frac{\frac{1}{2} \int_0^{R_{sc}} U_{\ell s}^2(r_s) \xi(r_c) dr_c}{\int_0^{R_{sc}} U_{\ell c}^2(r_c) dr_c}$$

$$\zeta_{n\ell}^{(s)} = \frac{\frac{1}{2} \int_0^{R_{ss}} U_{\ell s}^2(r_s) \xi(r_s) dr_s}{\int_0^{R_{ss}} U_{\ell s}^2(r_s) \xi(r_s) dr_s}$$

Note that the summation on  $n, \ell$  in equation III-13 must be included if there is any appreciable mixing of core states in our valence band wave functions.

### Splitting at $\Gamma_{15}$

As figure A4-1 indicates, the  $\Gamma_{15}$  state is split into a  $\Gamma_8^-$  (four fold degenerate) and a  $\Gamma_6^-$  (doubly degenerate) state, the  $\Gamma_8^-$  level lies highest. Since  $\Gamma_{15}$  is predominantly p-like (mostly  $\text{Cl}^-(3p)$  or  $\text{Br}^-(4p)$  with a small amount of  $\text{Ag}^+(5p)$ ), the splitting resembles the free ion  $j_{3/2} - j_{1/2}$  splitting in that the fourfold degenerate  $j_{3/2}$  ionic level lies above the doubly degenerate  $j_{1/2}$  ionic level.

The matrix elements (III-13) at  $\Gamma_{15}$  are:

$$\begin{aligned}
 (H_{SO})_{ij} = & \left\{ \sum_{m=-1}^1 \sum_{m'=-1}^1 \left[ \frac{C_{1m}^{*(i)} C_{1m'}^{(j)}}{|C_{1m}^{(i)}|^2} a_{1c} \zeta_{3P}^{(c)} \right]_{\text{at } \Gamma_{15}} (\vec{l} \cdot \vec{\sigma})_{1m,1m'}^{ij} \right. \\
 & \left. + \sum_{m=-1}^1 \sum_{m'=-1}^1 \left[ \frac{S_{1m}^{*(j)} S_{1m'}^{(j)}}{|S_{1m}^{(i)}|^2} a_{1s} \zeta_{5P}^{(s)} \right]_{\text{at } \Gamma_{15}} (\vec{l} \cdot \vec{\sigma})_{1m,1m'}^{ij} \right\}
 \end{aligned}$$

After substituting the coefficients given in Appendix Two, we obtain the spin-orbit matrix:

$$H_{SO} = \lambda \begin{bmatrix} 0 & -i & 0 & 0 & 0 & 1 \\ i & 0 & 0 & 0 & 0 & -i \\ 0 & 0 & 0 & -1 & i & 0 \\ 0 & 0 & -1 & 0 & i & 0 \\ 0 & 0 & -i & -i & 0 & 0 \\ 1 & i & 0 & 0 & 0 & 0 \end{bmatrix} \quad \text{at } \Gamma_{15}. \quad (\text{III-14})$$

$$\text{where } \lambda = a_{1c} \zeta_{3P}^{(c)} + a_{1s} \zeta_{5P}^{(s)}$$

By rearranging rows and columns, the secular determinant factors:

$$\det |H_{SO} - \epsilon I| = \begin{bmatrix} -\epsilon & -i\lambda & \lambda & 0 & 0 & 0 \\ i\lambda & -\epsilon & -i\lambda & 0 & 0 & 0 \\ \lambda & +i\lambda & -\epsilon & 0 & 0 & 0 \\ 0 & 0 & 0 & -\epsilon & -i\lambda & \lambda \\ 0 & 0 & 0 & i\lambda & -\epsilon & -i\lambda \\ 0 & 0 & 0 & \lambda & i\lambda & -\epsilon \end{bmatrix} = 0$$

with roots  $\epsilon = \begin{cases} +\lambda & \text{occurring 4 times} \\ -2\lambda & \text{occurring 2 times} \end{cases} \quad (\text{III-15})$

We approximate the one electron spin-orbit parameters by their free ion values. Thus, substituting

$$\begin{aligned} \text{Cl}^- (3p): \quad \zeta_{3p}^{(c)} &= .0030 && \text{from Waber's} && (\text{III-16}) \\ \text{Br}^- (4p): \quad \zeta_{4p}^{(B)} &= .0122 && \text{relativistic} && \\ &&& \text{solutions} && \\ \text{Ag}^+ (5p): \quad \zeta_{5p}^{(s)} &\simeq .0105 && \text{from Atomic Energy Levels.}^* && \end{aligned}$$

into III-15 we find that the  $\Gamma_{15}$  level is split into the two levels:  $+\epsilon, -2\epsilon$  where

$$\epsilon = \begin{cases} .0027 & \text{AgCl} \\ .0110 & \text{AgBr} \end{cases} \quad (\text{III-16})$$

### Splitting at $L_3$

The  $L_3$  state will be split into a (doubly degenerate)  $L_6^+$  state and singly degenerate  $L_4^+$  and  $L_5^+$  states, as shown in figure A4-1. The  $L_4^+$  and  $L_5^+$  states are degenerate with each other because of time reversal symmetry; therefore  $L_3$  will be split into only two levels by the spin-orbit interaction.

The wave function at  $L_3$  is composed mostly of  $\text{Cl}^- (3p)$  or  $\text{Br}^- (4p)$

---

\* Atomic Energy Levels, Vol. III, circular 467, U.S. Dept. of Commerce.

and  $\text{Ag}^+(5d)$  ionic-like function. After using equation III-13 to determine the matrix elements, we obtain the spin-orbit matrix

$$H_{\text{so}} = \frac{\lambda}{\sqrt{3}} \begin{bmatrix} 0 & i & 0 & \sqrt{2}\omega \\ -i & 0 & -\sqrt{2}\omega & 0 \\ 0 & -\sqrt{2}\omega^* & 0 & -i \\ -\sqrt{2}\omega^* & 0 & i & 0 \end{bmatrix} \quad \text{at } L_3 \quad (\text{III-17})$$

where  $\omega = e^{i\pi/4}$ , and

$$\lambda = \begin{cases} q_{1C} \zeta_{3p}^{(c)} - (K)_{\text{AgCl}} q_{2s} \zeta_{4d}^{(s)} & \text{for AgCl} \\ q_{1B} \zeta_{4p}^{(B)} - (K)_{\text{AgBr}} q_{2s} \zeta_{4d}^{(s)} & \text{for AgBr} \end{cases} \quad (\text{III-18})$$

The constant K is defined by

$$K = \sqrt{3} \left\{ \frac{(S_{22}^{*(1)} S_{22}^{(2)} - S_{2^{-2}}^{*(1)} S_{2^{-2}}^{(2)}) + (S_{21}^{*(1)} S_{21}^{(2)} - S_{2^{-1}}^{*(1)} S_{2^{-1}}^{(2)})}{\sum_{m=-2}^2 |S_{2m}^{(1)}|^2} \right\} \quad \text{at } L_3 \quad (\text{III-19})$$

for either crystal. The eigenvalues of the spin-orbit matrix at  $L_3$  are  $\epsilon = \pm\lambda$ .

It is interesting to note that the form of the splitting at  $L_3$  is quite different from that at  $\Gamma_{15}$ . First of all, at  $L_3$  the individual contributions of the two ions are of opposite sign, which will tend to reduce the size of the actual band splittings. Secondly, the

angular dependence of the  $\underline{d}$  portion of the wave function in the crystal will be distorted from that of the free ion by the cubic field. For this reason the constant  $K$  appears in equation III-18, and is then a measure of the cubic field strength in the crystal. Substituting the values of the  $S_{2m}^{(i)}$  (given in Appendix Two) in equation III-19, we find that

$$\begin{aligned} (K)_{\text{AgCl}} &= .67 \\ (K)_{\text{AgBr}} &= .83 \end{aligned} \tag{III-20}$$

which agrees with our previous reasoning, since the lattice spacing for AgBr is larger than that of AgCl (i.e., the cubic field strength is smaller).

Because our four spin-dependent functions transform as a basis for a reducible representation of the double group at  $L_3$ , the preceding analysis has only determined the energy splitting and gives no information about the symmetry labels of the split levels. In order to determine whether the  $L_6^+$  or  $L_4^+$  and  $L_5^+$  levels is highest, we must apply projection operators to the eigenfunctions of the spin-orbit matrix (equation III-17).

Details about the use of projection operators in this case are given in Appendix Five. There it is shown that the vector

$$\Psi = \begin{pmatrix} 3/2 \\ b \\ -3/2 \omega^* \\ b\omega^* \end{pmatrix} \quad \text{where } b = \sqrt{\frac{3}{2}} - \sqrt{\frac{3}{2}} i \\ \omega = e^{i \pi/4} \tag{III-21}$$

is an eigenvector of the spin-orbit matrix (III-17) with symmetry  $L_4^+$  and eigenvalue  $\epsilon = +\lambda$ . Consequently the  $L_5^+$  state also has energy  $\epsilon = +\lambda$  and the  $L_6^+$  state is associated with the level  $\epsilon = -\lambda$ .

Using the free ion spin orbit parameters obtained from Waber's calculation (for  $Ag^+(4d) \zeta_{4d}^{(s)} = .00935$ ) we obtain

$$\epsilon = \begin{cases} -.0032 & AgCl \\ +.0029 & AgBr \end{cases}$$

or equivalently

Table III-4

	$L_4^+$	$L_5^+$	$L_6^+$
AgCl	-.0032	-.0032	+.0032
AgBr	.0029	.0029	-.0029

Thus, in AgCl the  $L_6^+$  state lies highest, in AgBr the  $L_4^+$  and  $L_5^+$  states are highest.

III-5. Summary of Perturbations and final Results.

The results of the three perturbations are summarized in tables III-5 and III-6 for AgCl and AgBr respectively.

Table III-5 - AgCl

APW state	cubic field	mass vel.	spin orbit
$\Gamma_{15}$	0	.0002	$\Gamma_8^-$ : .0027 $\Gamma_6^-$ : -.0054
$L_3$	.0058	.0039	$L_6^+$ : .0032 $L_4^+, L_5^+$ : -.0032

Table III-6 AgBr

APW state	cubic field	mass-vel.	spin-orbit
$\Gamma_{15}$	0	.0009	$\Gamma_8^-$ : .0110
			$\Gamma_6^-$ : -.0220
$L_3$	.0033	.-269	$L_4^+, L_5^+$ : .0029
			$L_6^+$ : -.0029

By referring to Tables III-5 and III-6 we see that for both crystals the  $L_3$  state (using single group notation) is the highest point in the valence band after all perturbations have been applied. Schematic drawings (not to scale) of the perturbation effects for the  $\Gamma_{15}$  and  $L_3$  states are shown in figures III-1 and III-2 for AgCl and AgBr respectively.

As we mentioned previously, the quantity  $\Delta$  will be used to compare our results with experiment. From Tables III-5 and III-6 we find:

	$(\Delta)_{APW}$	$(\Delta)_{APW} + \text{perturbation}$	$\Delta \text{ experimental} = E_g - E_{ig}$
AgCl	1.220 ev	1.843 ev	1.880 ev.
AgBr	1.049 ev	1.336 ev	1.61 ev.

In other words, after fitting our bands gap,  $E_g$  to the

Figure III-1  
 Perturbation Effects in AgCl

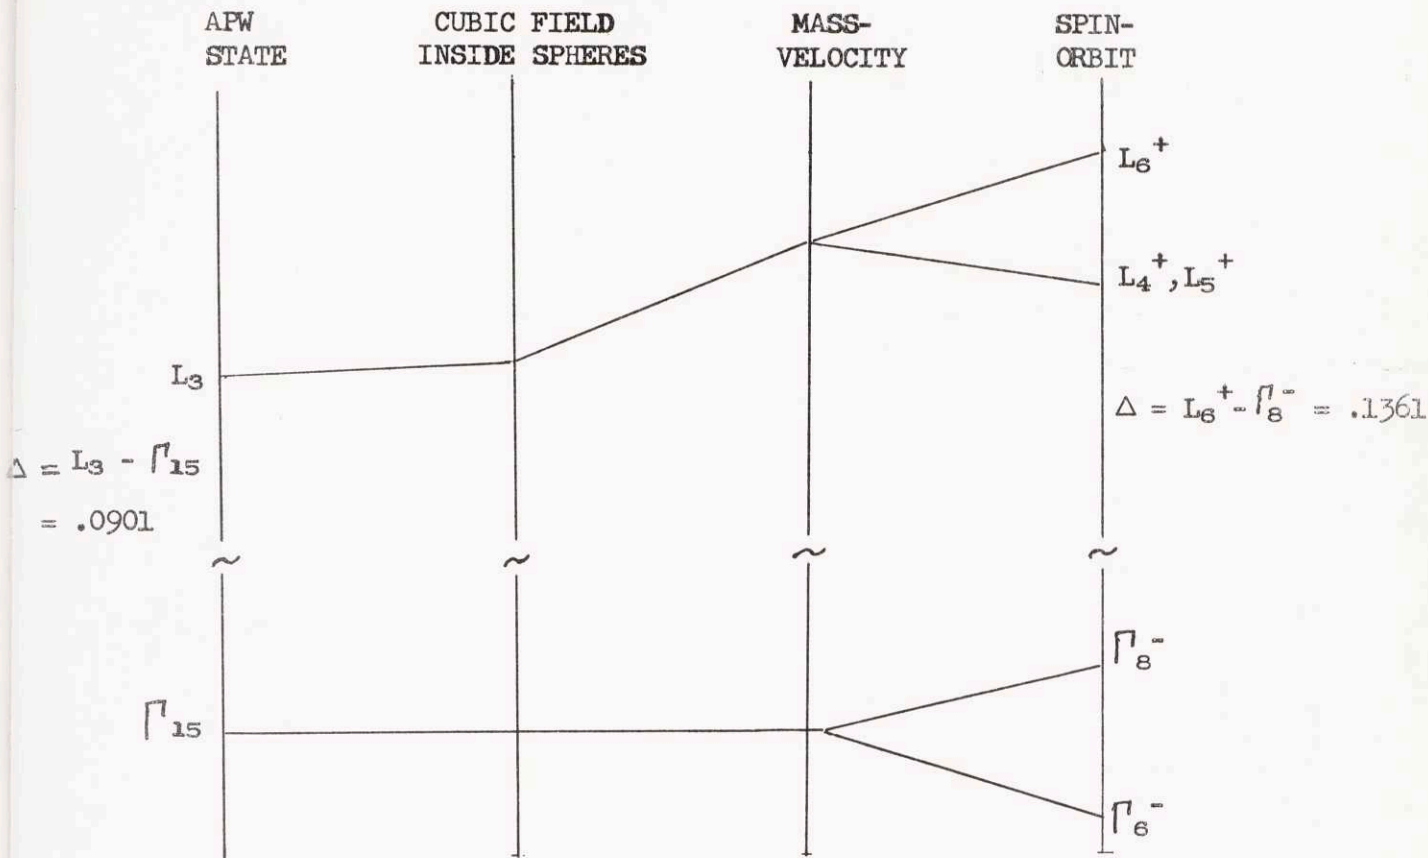

Figure III-2

Perturbation Effects in AgBr

experimental values we obtain the indirect gap  $E_{ig} = E_g - \Delta$  :

	$(E_{ig})_{\text{calc.}}$	$(E_{ig})_{\text{experimental}}$
AgCl	3.29 ev.	3.25 ev.
AgBr	2.95 ev.	2.68 ev.

At this point it should be mentioned that the values for  $E_{ig}$  given above are threshold energies found from optical absorption measurements and really do not correspond to transitions between electron states in the crystal, but transitions involving exciton formation. To determine  $E_{ig}$  for electronic transitions from the valence band to the conduction band one must take into account the binding energy of the exciton. However, not only is the binding energy of the exciton known only approximately, but, in addition, surface effects may further distort the exciton levels.<sup>10</sup> Thus, because we can only obtain crude approximations for the exciton binding energies, the true value of  $E_{ig}$  must be considered somewhat uncertain. A reasonable estimate of the exciton binding energy is a few tenths of an electron volt; consequently, the corrected sizes of the indirect band gaps are:  $E_{ig} = 3.4$  ev in AgCl and  $E_{ig} = 2.9$  ev. in AgBr.

We may conclude that the APW bands calculated after varying one parameter,  $V_0$ , certainly are in fairly good agreement with experimental facts. Moreover, even though the effects of some of the major perturbations have been calculated only approximately, at least the

correction terms tend to decrease the size of discrepancies between the APW calculation and experimental results. Because of the uncertainty in the true value of the indirect band gap, a precise comparison of the difference between the calculations and experiments is impossible, but the discrepancies are only of the order of one or two tenths of an electron volt (i.e. the error in the calculation of the indirect band gap is 5% of the size of the gap).

Appendix One - Numerical Details of APW Calculations

Cube edge,  $a = 10.46$  atomic units

$$\text{Madelung potential, } V_M = \pm \frac{2\alpha}{a/2} = \pm \frac{4\alpha}{a} \quad \text{where } \alpha = 1.747558$$

$$V_M = \pm 0.668282217$$

sphere radii are  $(R_s)_{Ag^+} = 2.60$  a.u.,  $(R_s)_{Cl^-} = 2.63$  a.u.

ionicities are:  $Ag^{\dagger} : +1$ ;  $Cl^- : -1$ .

$$V_0 = -.579357$$

TABLE A1-1

Numerical potential used to obtain energy bands for silver-chloride.

Potential used is tabular value -  $V_{\text{Shift}}$ , where  $V_{\text{Shift}} = V_M - V_0$ .

For chlorine  $V_{\text{Shift}} = 1.088925$ , for silver  $V_{\text{Shift}} = 1.247639$ .

TABLE A1-3

Silver Chloride Energy Band States and Charge Densities

Here we list the values of  $\epsilon(\vec{k})$  calculated by the APW method ( $\vec{k}$  is given in units of  $\frac{\pi}{a}$ ). Also, for points of major interest in the valence band the "charge density" within each sphere and between spheres is given. This "charge density" within a given sphere is the total amount of charge in that sphere which can be associated with a particular  $\ell$  value. The charge between spheres is labeled "plane wave". Finally, only the dominant contributions to the charge density are tabulated below even though the calculations were performed for  $\ell = 0, \dots, 12$ .

LOWEST CONDUCTION BAND

4k	Symmetry	APW Energy (in Rydbergs)
0,0,0	$\Gamma_1$	.1569
0,2,0	$\Delta_1$	.2200
0,4,0	$\Delta_1$	.3029
0,6,0	$\Delta_1$	.3199
0,8,0	$X_1$	.3005

AgBr Calculation

Cube edge,  $a = 10.926$  atomic units

$$\text{Madelung potential, } V_M = \pm \frac{2\alpha}{a\sqrt{2}} = \pm \frac{4\alpha}{a} = \pm .654423576$$

$$\text{Sphere radii are: } (R_s)_{\text{Ag}}^+ = 2.6105 \text{ a.u.}$$

$$(R_s)_{\text{Br}}^- = 2.8525$$

ionicities are:  $\text{Ag}^+ : +1$  ;  $\text{Br}^- : -1$

$$V_0 = .69465$$

TABLE A1-4

Numerical potential used to obtain energy bands for silver-bromide.

Potential used is tabular value -  $V_{\text{Shift}}$ , where  $V_{\text{Shift}} = V_M - V_0$ .

For bromine  $V_{\text{Shift}} = .0402300$ , for silver  $V_{\text{Shift}} = 1.34907000$

TABLE A1-6

Silver Bromide Energy Band States and Charge Densities

Here we list the values of  $\epsilon(\vec{k})$  calculated by the APW method ( $\vec{k}$  is given in units of  $\frac{\pi}{a}$ ). Also, for points of major interest in the valence band the "charge density" within each sphere and between spheres is given. This "charge density" within a given sphere is the total amount of charge in that sphere which can be associated with a particular  $\ell$  value. The charge between spheres is labeled "plane wave". Finally, only the dominant contributions to the charge density are tabulated below even though the calculations were performed for  $\ell = 0, \dots, 12$ .

LOWEST CONDUCTION BAND

where

$$S = .046648408$$

$$B = 1.0447396$$

$$S_{2-2}^{(2)} = -2iS$$

$$S_{2-1}^{(2)} = (1 + i)S$$

$$S_{20}^{(2)} = -12S$$

$$S_{21}^{(2)} = (-1 + i)S$$

$$S_{22}^{(2)} = 2iS$$

$$B_{1-1}^{(2)} = (-1 + i)B$$

$$B_{10}^{(2)} = -2\sqrt{2}B$$

$$B_{11}^{(2)} = -(1 + i)B$$

Appendix Three - Operations of the Cubic Group,  $O_h$ .

The operations of the cubic group listed here are those defined by Slater in "Quantum Theory of Molecules and Solids, Volume One".

$R_1 \psi(x, y, z) = \psi(x, y, z)$	$R_{25} \psi(x, y, z) = \psi(-x, -y, -z)$
$R_2 \psi(x, y, z) = \psi(x, -y, -z)$	$R_{26} \psi(x, y, z) = \psi(-x, y, z)$
$R_3 \psi(x, y, z) = \psi(-x, y, z)$	$R_{27} \psi(x, y, z) = \psi(x, -y, -z)$
$R_4 \psi(x, y, z) = \psi(-x, -y, z)$	$R_{28} \psi(x, y, z) = \psi(x, y, -z)$
$R_5 \psi(x, y, z) = \psi(y, z, x)$	$R_{29} \psi(x, y, z) = \psi(-y, -z, -x)$
$R_6 \psi(x, y, z) = \psi(-y, z, -x)$	$R_{30} \psi(x, y, z) = \psi(y, -z, x)$
$R_7 \psi(x, y, z) = \psi(-y, -z, x)$	$R_{31} \psi(x, y, z) = \psi(y, z, x)$
$R_8 \psi(x, y, z) = \psi(y, -z, -x)$	$R_{32} \psi(x, y, z) = \psi(-y, z, x)$
$R_9 \psi(x, y, z) = \psi(z, x, y)$	$R_{33} \psi(x, y, z) = \psi(-z, -x, -y)$
$R_{10} \psi(x, y, z) = \psi(-z, -x, y)$	$R_{34} \psi(x, y, z) = \psi(z, x, -y)$
$R_{11} \psi(x, y, z) = \psi(z, -x, -y)$	$R_{35} \psi(x, y, z) = \psi(-z, x, y)$
$R_{12} \psi(x, y, z) = \psi(-z, x, -y)$	$R_{36} \psi(x, y, z) = \psi(z, -x, y)$
$R_{13} \psi(x, y, z) = \psi(-x, z, -y)$	$R_{37} \psi(x, y, z) = \psi(x, -z, y)$
$R_{14} \psi(x, y, z) = \psi(-x, -z, y)$	$R_{38} \psi(x, y, z) = \psi(x, z, -y)$
$R_{15} \psi(x, y, z) = \psi(-z, -y, x)$	$R_{39} \psi(x, y, z) = \psi(z, y, -x)$
$R_{16} \psi(x, y, z) = \psi(z, -y, -x)$	$R_{40} \psi(x, y, z) = \psi(-z, y, x)$
$R_{17} \psi(x, y, z) = \psi(y, -x, -z)$	$R_{41} \psi(x, y, z) = \psi(-y, x, z)$
$R_{18} \psi(x, y, z) = \psi(-y, x, -z)$	$R_{42} \psi(x, y, z) = \psi(y, -x, z)$
$R_{19} \psi(x, y, z) = \psi(x, z, y)$	$R_{43} \psi(x, y, z) = \psi(-x, -z, -y)$
$R_{20} \psi(x, y, z) = \psi(x, -z, -y)$	$R_{44} \psi(x, y, z) = \psi(-x, z, y)$
$R_{21} \psi(x, y, z) = \psi(z, y, x)$	$R_{45} \psi(x, y, z) = \psi(-z, -y, -x)$
$R_{22} \psi(x, y, z) = \psi(-z, y, -x)$	$R_{46} \psi(x, y, z) = \psi(z, -y, x)$
$R_{23} \psi(x, y, z) = \psi(y, x, z)$	$R_{47} \psi(x, y, z) = \psi(-y, -x, -z)$
$R_{24} \psi(x, y, z) = \psi(-y, -x, z)$	$R_{48} \psi(x, y, z) = \psi(y, x, -z)$

Appendix Four - Interband Transitions

A- IV-1 Introduction

The transition probability for an electronic transition from an initial state  $\underline{i}$  to a final state  $\underline{f}$  is proportional to  $|H'_{fi}|^2$  where

$$H'_{fi} = \int \psi_{\vec{k}_f}^* H' \psi_{\vec{k}_i} dv \quad (A4-1)$$

Here  $\psi_{\vec{k}_f}$  and  $\psi_{\vec{k}_i}$  are the final and initial Bloch wave functions for the electron in the crystal.  $H'$  is the interaction that mixes the two states.

For direct optical transitions,  $H'$  is the electric dipole operator

$$H' = \frac{-ieh}{mc} \vec{A} \cdot \vec{\nabla} .$$

Writing the vector potential in the form

$$\vec{A} = \vec{A}_0 e^{i \vec{k} \cdot \vec{r}} \quad (\vec{A}_0 = \text{constant vector in the direction of polarization})$$

we obtain

$$H' = \frac{-ieh}{mc} e^{i \vec{k} \cdot \vec{r}} \vec{A}_0 \cdot \vec{\nabla} \quad (A4-2)$$

which has the form of a Bloch wave.

The interaction for the scattering of an electron by a phonon is

$$(A4-3) \quad H' = \vec{u} \cdot \vec{\nabla} V(\vec{r}) \quad \text{where} \quad \begin{aligned} \vec{u} &= \text{lattice displacement} \\ &= \vec{e} e^{i \vec{k} \cdot \vec{r}} \\ V(\vec{r}) &= \text{crystalline potential} \end{aligned}$$

and also has the Bloch form.

Thus for either type of transition, the matrix element is

$$H'_{f_i} = \int \psi_{\vec{k}_f}^* H'_{\vec{k}} \psi_{\vec{k}_i} dv \quad (A4-4)$$

where  $H'_{\vec{k}}$  is a Bloch wave. As a consequence of **translational invariance** we have the usual selection rule:

$$-\vec{k}_f + \vec{k} + \vec{k}_i = \begin{cases} 0 \\ \text{or} \\ \text{a vector of the} \\ \text{reciprocal lattice} \end{cases} \quad (A4-5)$$

We now discuss the selection rules that follow from the rotational invariance of the crystal.

Let:

$\psi_{\vec{k}_f}^{(\alpha)}$  transform as a basis partner for the  $\alpha^{\text{th}}$  irreducible representation of the group of  $\vec{k}_f$ .

$\psi_{\vec{k}_f}^{(\beta)}$  transform as a basis partner for the  $\beta^{\text{th}}$  irreducible representation of the group of  $\vec{k}$ .

$\psi_{\vec{k}_f}^{(\gamma)}$  transform as a basis partner for the  $\gamma^{\text{th}}$  irreducible representation of the group of  $\vec{k}_i$ .

Then from group theoretical arguments<sup>11</sup> it may be deduced that the matrix element  $H'_{f_i}$  vanishes unless the direct product representation

$$\Gamma^{*(\alpha)} \times \Gamma^{(\beta)} \times \Gamma^{(\gamma)} \quad (A4-6)$$

contains the identity representation in its decomposition. Since

$\vec{k}_f$ ,  $\vec{k}$ , and  $\vec{k}_i$  will in general belong to different groups, the direct

product group contains only their common elements. The number of times that the identity representation is contained in the decomposition of the direct product is given by

$$\frac{1}{g} \sum_{\ell=1}^g \chi^{*(\alpha)}(R_\ell) \chi^{(\beta)}(R_\ell) \chi^{(\gamma)}(R_\ell) \quad (A4-7)$$

where  $R_\ell = \ell^{\text{th}}$  common element of the groups  $\vec{k}_i$ ,  $\vec{k}$ , and  $\vec{k}_f$

$\chi^{(\alpha)}(R_\ell)$  = character of the element  $R_\ell$  for the  $\alpha^{\text{th}}$  irreducible representation. (Similarly for  $\chi^{(\beta)}(R_\ell)$  and  $\chi^{(\gamma)}(R_\ell)$ ).

$g$  = number of common elements,  $R_\ell$ .

Note that the order of the factors in either A4-6 or A4-7 is immaterial. If the sum A4-7 is zero, then the matrix element  $H_{fi}$  vanishes and the corresponding transition is forbidden. Otherwise the transition is allowed.

In general, to perform the sum on group elements (equation A4-7), one must consider the representations of the entire space groups, but if (as in the present case of the NaCl structure) the space groups do not contain glide planes or screw displacements (i.e. symmorphic space groups), only the appropriate point group representations are required. Thus for the three main symmetry directions we need only the character tables for the groups  $O_h$  (for the point  $\Gamma$ ),  $C_{2v}$  (for the  $\Sigma$  direction and the point K),  $C_{3v}$  (for the  $\Lambda$  direction),  $D_{3d}$  (for the point L),  $C_{4v}$  (for the  $\Delta$  direction), and  $D_{4h}$  (for the point X). The character tables for these groups are given at the end of this appendix

in tables A4-1 to A4-6. In these tables barred operations correspond to an additional rotation by  $2\pi$ . After each character table we give the multiplication table for the direct products of the different irreducible representations of that group.

For the groups that contain the inversion operation ( $O_h$ ,  $D_{4h}$ ,  $D_{3d}$ ) the multiplication table is given only for those representations even on inversion. To determine the decomposition of the direct product of  $\Gamma_i^\pm \times \Gamma_j^\pm$  (where the plus sign means even on inversion, the minus sign means odd on inversion), we use the rule that the product of two even (or two odd) representations is even; the product of an even representation and an odd representation is odd. For example, from table A4-1 we have:  $\Gamma_{12} \times \Gamma_8^+ = \Gamma_6^+ + \Gamma_7^+ + \Gamma_8^+$ ; therefore  $\Gamma_{12} \times \Gamma_8^- = \Gamma_6^- + \Gamma_7^- + \Gamma_8^-$ .

Before proceeding with the calculations, it is important to remember that in general the addition of spin in the Hamiltonian and wave functions will sometimes alter selection rules. For this reason, we consider the problem of determining the selection rules in both cases: first without spin, and then with spin added.

#### A- IV-2 - Selection Rules Without Spin

##### (a) Vertical Transitions

For vertical (or direct optical) transitions we have, to excellent approximation,  $\vec{k}_f = \vec{k}_i$ , or  $\vec{k} = 0$  in equation A4-5. Thus one studies the direct product  $\Gamma^{(\alpha)} \times \Gamma_{15} \times \Gamma^{(\beta)}$  since the interaction (light) behaves like an ordinary vector. Because spin is ignored, we use only

single valued representations in our calculations.

Point  $\Gamma$  (Group  $O_h$ ).

Here all three vectors belong to the same group. Hence, from the multiplication table A4-1 we have:

$$\text{transition } \Gamma_1 \rightarrow \Gamma_{15}: \Gamma_1 \times \Gamma_{15} \times \Gamma_{15} = \Gamma_1 + \Gamma_2 + \Gamma_{15} + \Gamma'_{25}$$

Contains identity representation  $\Gamma_1$  and is therefore allowed

$$\Gamma_1 \rightarrow \Gamma_{12} : \Gamma_1 \times \Gamma_{15} \times \Gamma_{12} = \Gamma_{15} + \Gamma_{25} \quad \therefore \text{forbidden}$$

$$\Gamma_1 \rightarrow \Gamma'_{25} : \Gamma_1 \times \Gamma_{15} \times \Gamma'_{25} = \Gamma'_2 + \Gamma'_{12} + \Gamma_{15} + \Gamma_{25} \\ \therefore \text{forbidden}$$

$$\Gamma_1 \rightarrow \Gamma_{15} : \Gamma_{15} \times \Gamma_{15} \times \Gamma_{15} = \Gamma'_1 + 2\Gamma'_2 + \Gamma'_{12} + 3\Gamma_{15} + 3\Gamma_{25} \\ \therefore \text{forbidden}$$

$$\Gamma_{15} \rightarrow \Gamma'_{25} : \Gamma_{15} \times \Gamma_{15} \times \Gamma'_{25} = \Gamma_1 + 2\Gamma_2 + 3\Gamma'_{15} + 3\Gamma'_{25} \\ \therefore \text{allowed}$$

Along  $\Delta$  (Group  $C_{4v}$ )

Using equation A4-7 and table A4-2, we find that only the direct products  $\Delta_1 \times \Gamma_{15}$  and  $\Delta_5 \times \Gamma_{15}$  contain the identity representation  $\Delta_1$ . Thus, the transition  $\Delta_i \rightarrow \Delta_j$  is allowed only if  $\Delta_i \times \Delta_j$  contains either  $\Delta_1$  or  $\Delta_5$ . From the multiplication table A4-2 we find that the allowed transitions are:

$\Delta_1 \longrightarrow \Delta_1$	since	$\Delta_1 \times \Delta_1 = \Delta_1$
$\Delta_1 \longrightarrow \Delta_5$	"	$\Delta_1 \times \Delta_5 = \Delta_5$
$\Delta_2 \longrightarrow \Delta_2$	"	$\Delta_2 \times \Delta_2 = \Delta_1$
$\Delta_2 \longrightarrow \Delta_5$	"	$\Delta_2 \times \Delta_5 = \Delta_5$
$\Delta'_2 \longrightarrow \Delta'_2$	"	$\Delta'_2 \times \Delta'_2 = \Delta_1$
$\Delta'_2 \longrightarrow \Delta_5$	"	$\Delta'_2 \times \Delta_5 = \Delta_5$
$\Delta_5 \longrightarrow \Delta_5$	"	$\Delta_5 \times \Delta_5 = \Delta_1 + \Delta'_2 + \Delta_2 + \Delta'_2$

All other direct transitions  $\Delta_i \longrightarrow \Delta_j$  are forbidden

At X (Group  $D_{4h}$ )

From equation A4-7 and Table A4-3 we find that only the direct products  $\Gamma_{15} \times X'_4$  and  $\Gamma_{15} \times X'_5$  contain the identity representation,  $X_1$ . The allowed transitions  $X_i \longrightarrow X_j$  must contain either  $X'_4$  or  $X'_5$  in the direct product  $X_i \times X_j$ . By inspection of Table A4-3, we obtain:

$X_1 \longrightarrow X'_4$	} Allowed transitions at X
$X_1 \longrightarrow X'_5$	
$X_2 \longrightarrow X'_5$	
$X_3 \longrightarrow X'_5$	
$X'_4 \longrightarrow X_5$	
$X_4 \longrightarrow X'_5$	
$X_5 \longrightarrow X'_5$	

All other direct transitions at X are forbidden

Along  $\Sigma$  and at K (Group  $C_{2v}$ )

Only the direct products  $\Sigma_1 \times \Gamma_{15}$ ,  $\Sigma_3 \times \Gamma_{15}$ , and  $\Sigma_4 \times \Gamma_{15}$  contain the identity representation,  $\Sigma_1$ . Thus, allowed transitions  $\Sigma_i \longrightarrow \Sigma_j$  must contain  $\Sigma_1$ ,  $\Sigma_3$  or  $\Sigma_4$  in the direct product  $\Sigma_i \times \Sigma_j$ . From table A4-4, we have:

$$\left. \begin{array}{l} \Sigma_1 \longrightarrow \Sigma_3 \\ \Sigma_1 \longrightarrow \Sigma_4 \\ \Sigma_2 \longrightarrow \Sigma_2 \\ \Sigma_2 \longrightarrow \Sigma_3 \\ \Sigma_2 \longrightarrow \Sigma_4 \\ \Sigma_3 \longrightarrow \Sigma_3 \\ \Sigma_4 \longrightarrow \Sigma_4 \end{array} \right\} \text{allowed} \left\{ \begin{array}{l} K_1 \longrightarrow K_3 \\ K_1 \longrightarrow K_4 \\ K_2 \longrightarrow K_2 \\ K_2 \longrightarrow K_3 \\ K_2 \longrightarrow K_4 \\ K_3 \longrightarrow K_3 \\ K_4 \longrightarrow K_4 \end{array} \right.$$

Also, the only forbidden transitions are:

$$\left. \begin{array}{l} \Sigma_1 \longrightarrow \Sigma_2 \\ \Sigma_3 \longrightarrow \Sigma_4 \end{array} \right\} \text{forbidden} \left\{ \begin{array}{l} K_1 \longrightarrow K_2 \\ K_3 \longrightarrow K_4 \end{array} \right.$$

Along  $\Lambda$  (Group  $C_{3v}$ )

Here only the direct product  $\Lambda_3 \times \Gamma_{15}$  contains the identity representation  $\Lambda_1$ . The allowed transitions  $\Lambda_i \longrightarrow \Lambda_j$  must contain  $\Lambda_3$  in the direct product  $\Lambda_i \times \Lambda_j$ . By inspection of table A4-5 we find the allowed transitions are:

$$\left. \begin{array}{l} \Lambda_1 \longrightarrow \Lambda_3 \\ \Lambda_3 \longrightarrow \Lambda_3 \end{array} \right\} \text{allowed}$$

but

$$\Lambda_1 \longrightarrow \Lambda_1 \quad \text{forbidden}$$

At L (Group D<sub>3d</sub>)

At the point L, only the direct products L'<sub>2</sub> x  $\Gamma_{15}$  and L'<sub>3</sub> x  $\Gamma_{15}$  contain the identity representation L<sub>1</sub>. As in the previous cases, the transition L<sub>1</sub>  $\longrightarrow$  L<sub>j</sub> will be allowed only if the direct product L<sub>1</sub> x L<sub>j</sub> contains L'<sub>2</sub> or L'<sub>3</sub>. From table A4-6, we find that the allowed transitions are:

$$\begin{array}{l}
 L_1 \longrightarrow L'_2 \\
 L_1 \longrightarrow L'_3 \\
 L_2 \longrightarrow L'_3 \\
 L_3 \longrightarrow L'_2 \\
 L_3 \longrightarrow L'_3
 \end{array}
 \left. \vphantom{\begin{array}{l} L_1 \\ L_1 \\ L_2 \\ L_3 \\ L_3 \end{array}} \right\} \text{ allowed}$$

(b) Indirect Transitions

Indirect transitions are the result of an electron being scattered by a phonon from an initial state  $\vec{k}_i$ , to an intermediate state  $\vec{k}$  and then emitting or absorbing a photon to arrive at a final state  $\vec{k}_f$ . The second step of the process is a direct transition ( $\vec{k}_f = \vec{k}$ ) and governed by the selection rules determined in the previous section. We now study the phonon assisted transitions, i.e. those transitions in which an electron along a particular band is scattered by a phonon either to the point  $\Gamma$  or to the edge of the Brillouin zone.

Yanagawa<sup>12</sup> has shown that the only allowed phonons for an NaCl structure are:

$\Delta_1$ and $\Delta_5$	in the $\Delta$ direction
$\Sigma_1$ , $\Sigma_3$ , and $\Sigma_4$	in the $\Sigma$ direction
$\Lambda_1$ and $\Lambda_3$	in the $\Lambda$ direction

In order to determine whether or not an electron-phonon interaction is possible along a particular direction, we again inspect the decomposition of the direct product  $\Gamma^*(\alpha) \times \Gamma(\beta) \times \Gamma(\gamma)$  and see if it contains the identity representation. However, for the electron-phonon interaction we really have very little work to do. In each direction, one of the allowed phonons has the identity representation for that particular direction. Therefore the representation of the direct product of (electron representation)x(phonon representation) will always contain the irreducible representation of the electron along a given band. Since the symmetry of the electron band must be compatible with that of the associated state at  $\Gamma$  or the zone edge, the decomposition of the direct product will always contain the identity representation. Thus we may conclude that the electron-phonon interaction is allowed for all bands; selection rules for the total indirect transition being those of the "direct" portion of the two step process.

A- IV-3 Transitions when Hamiltonian is spin dependent

(a) Direct Transitions

We now consider the transitions when the Hamiltonian is spin dependent because of the addition of spin-orbit coupling. The wave functions are two component spinors formed from linear combinations of the unperturbed APW functions each multiplied by a spinor,  $\alpha$  or  $\beta$  (where  $\alpha = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$ ,  $\beta = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$ ). Defining  $D_{1/2}$  as the spinor representation, we find that the direct product  $D_{1/2} \times \Gamma^{(\sigma)}$  may be decomposed into a sum of irreducible representations of the double group.<sup>13</sup> These are:

at  $\Gamma$  :

$$\begin{aligned}
 D_{1/2} \times \Gamma_1 &= \Gamma_6^+ \\
 D_{1/2} \times \Gamma_2 &= \Gamma_7^+ \\
 D_{1/2} \times \Gamma_{12} &= \Gamma_8^+ \\
 D_{1/2} \times \Gamma_{15}' &= \Gamma_6^+ + \Gamma_8^+ \\
 D_{1/2} \times \Gamma_{25}' &= \Gamma_7^+ + \Gamma_8^+ \\
 D_{1/2} \times \Gamma_1' &= \Gamma_6^- \\
 D_{1/2} \times \Gamma_2' &= \Gamma_7^- \\
 D_{1/2} \times \Gamma_{12}' &= \Gamma_8^- \\
 D_{1/2} \times \Gamma_{15} &= \Gamma_6^- + \Gamma_8^- \\
 D_{1/2} \times \Gamma_{25} &= \Gamma_7^- + \Gamma_8^-
 \end{aligned}$$

+ means that the representation has even parity

- means that the representation has odd parity

along  $\Delta$ :

$$\begin{aligned}D_{1/2} \times \Delta_1 &= \Delta_6 \\D_{1/2} \times \Delta'_1 &= \Delta_6 \\D_{1/2} \times \Delta_2 &= \Delta_7 \\D_{1/2} \times \Delta'_2 &= \Delta_7 \\D_{1/2} \times \Delta_5 &= \Delta_6 + \Delta_7\end{aligned}$$

at X:

$$\begin{aligned}D_{1/2} \times X_1 &= X_6^+ & D_{1/2} \times X_1 &= X_6^- \\D_{1/2} \times X_2 &= X_7^+ & D_{1/2} \times X_2' &= X_7^- \\D_{1/2} \times X_3 &= X_7^+ & D_{1/2} \times X_3' &= X_7^- \\D_{1/2} \times X_4 &= X_6^+ & D_{1/2} \times X_4' &= X_6^- \\D_{1/2} \times X_5 &= X_6^+ + X_7^+ & D_{1/2} \times X_5' &= X_6^- + X_7^-\end{aligned}$$

along  $\Sigma$  and at K:

$$\begin{aligned}D_{1/2} \times \Sigma_1 &= \Sigma_5 & D_{1/2} \times K_1 &= K_5 \\D_{1/2} \times \Sigma_2 &= \Sigma_5 & D_{1/2} \times K_2 &= K_5 \\D_{1/2} \times \Sigma_3 &= \Sigma_5 & D_{1/2} \times K_3 &= K_5 \\D_{1/2} \times \Sigma_4 &= \Sigma_5 & D_{1/2} \times K_4 &= K_5\end{aligned}$$

along  $\Lambda$ :

$$\begin{aligned}D_{1/2} \times \Lambda_1 &= \Lambda_6 \\D_{1/2} \times \Lambda_2 &= \Lambda_6 \\D_{1/2} \times \Lambda_3 &= \Lambda_4 + \Lambda_5 + \Lambda_6\end{aligned}$$

at L:

$$D_{1/2} \times L_1 = L_6^+$$

$$D_{1/2} \times L_2 = L_6^+$$

$$D_{1/2} \times L_3 = L_4^+ + L_5^+ + L_6^+$$

$$D_{1/2} \times L_1' = L_6^-$$

$$D_{1/2} \times L_2' = L_6^-$$

$$D_{1/2} \times L_3' = L_4^- + L_5^- + L_6^-$$

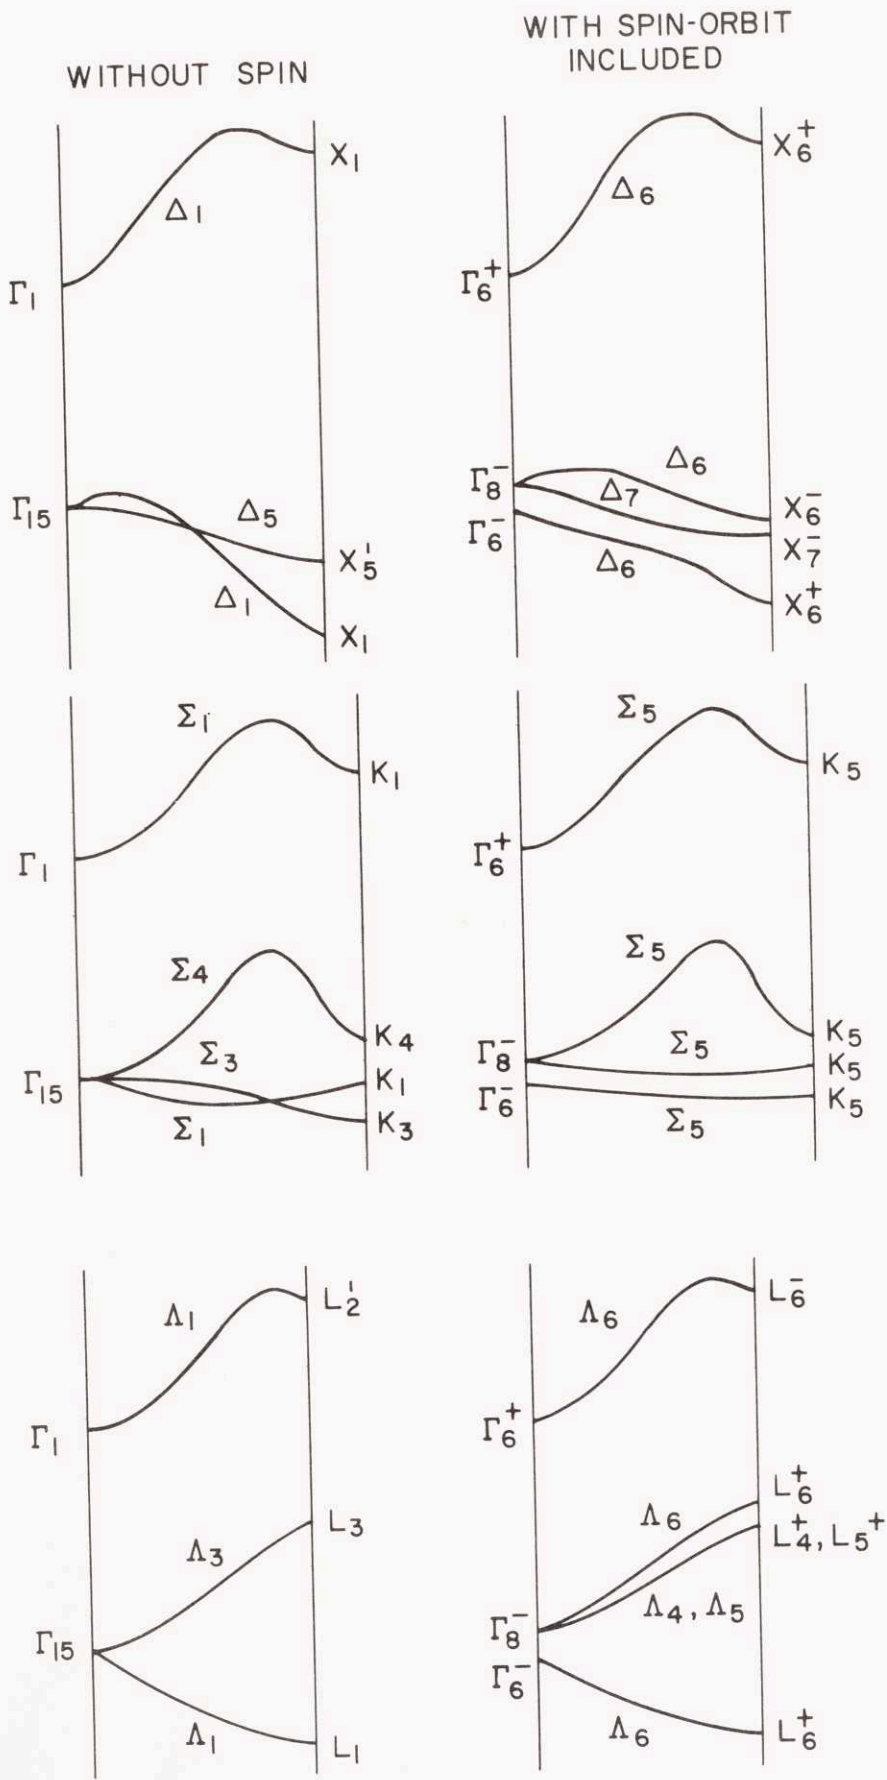

The APW bands will be altered when spin-orbit coupling is included in the Hamiltonian. At some points in the Brillouin zone, an unperturbed band will be split into several distinct bands; in some cases the original APW states are only shifted slightly because of the spin-orbit interaction. The upper valence and lower conduction bands (for AgCl) with and without spin orbit coupling included are sketched in Figure A4-1 for the three symmetry directions. Note that the drawing is not to scale and the spin orbit splittings have been greatly magnified.

The addition of spin-orbit coupling has reduced the number of possible symmetries in our bands. Consequently, since more bands have like symmetry, there is a great deal more mixing of states than before. We now show that because of this additional mixing of states, almost all direct transitions are allowed. The only forbidden direct transitions are those between states of the same parity (at the points  $\Gamma$ , X, and L which are parity eigenstates) and the transition  $\Gamma_6^\pm \rightarrow \Gamma_7^\mp$  at  $\Gamma$ .

The representations at  $\Gamma$  are  $\Gamma_6^\pm$ ,  $\Gamma_7^\pm$ ,  $\Gamma_8^\pm$ . Since the parity of the electric dipole interaction is odd, we can have non-zero matrix elements only between states of opposite parity.

The direct products  $\Gamma_i^\pm \times \Gamma_j^\mp$  ( $i, j = 6, 7, 8$ ) may be decomposed into the irreducible representations of the single group (see Table A4-1). In order that the transition  $\Gamma_i^\pm \rightarrow \Gamma_j^\mp$  be allowed, this decomposition of this direct product must contain the representation  $\Gamma_{15}$  since the interaction has symmetry  $\Gamma_{15}$ . From Table A4-1 we find that;

UPPER VALENCE AND LOWEST CONDUCTION BANDS WITH AND WITHOUT SPIN-ORBIT INTERACTION

$\Gamma_6^+$	$\times$	$\Gamma_6^+$	$=$	$\Gamma_{1'}$	$+$	$\Gamma_{15}$	allowed				
$\Gamma_6^+$	$\times$	$\Gamma_7^+$	$=$	$\Gamma_{2'}$	$+$	$\Gamma_{25}$	forbidden				
$\Gamma_6^+$	$\times$	$\Gamma_8^+$	$=$	$\Gamma_{12'}$	$+$	$\Gamma_{15}$	$+$	$\Gamma_{25}$	allowed		
$\Gamma_7^+$	$\times$	$\Gamma_7^+$	$=$	$\Gamma_{1'}$	$+$	$\Gamma_{15}$	allowed				
$\Gamma_7^+$	$\times$	$\Gamma_8^+$	$=$	$\Gamma_{12'}$	$+$	$\Gamma_{15}$	$+$	$\Gamma_{25}$	allowed		
$\Gamma_8^+$	$\times$	$\Gamma_8^+$	$=$	$\Gamma_{1'}$	$+$	$\Gamma_{2'}$	$+$	$2 \Gamma_{15}$	$+$	$2 \Gamma_{25}$	allowed

along  $\Delta$

Here the possible symmetries are now  $\Delta_6$  and  $\Delta_7$ . Since the direct products  $\Delta_6 \times \Delta_6$ ,  $\Delta_6 \times \Delta_7$  and  $\Delta_7 \times \Delta_7$  all contain  $\Delta_1$  or  $\Delta_5$ , every transition is allowed.

at X.

The decomposition of the direct product  $X_i^{\pm} \times X_j^{\mp}$  must contain either  $X_4'$  or  $X_5'$ . From Table A4-3, we see that the direct products  $X_6^{\pm} \times X_5^{\mp}$ ,  $X_6^{\pm} \times X_7^{\mp}$ ,  $X_7^{\pm} \times X_7^{\mp}$  all contain  $X_4'$  or  $X_5'$  and therefore every parity allowed transition is possible.

along  $\Sigma$  and K

Here the only possible symmetry is  $\Sigma_5$  (or  $K_5$ ). Since  $\Sigma_5 \times \Sigma_5 = \Sigma_1 + \Sigma_2 + \Sigma_3 + \Sigma_4$ , all transitions are allowed.

along  $\Lambda$

The allowed symmetries are  $\Lambda_4$ ,  $\Lambda_5$ , and  $\Lambda_6$ , and the decomposition of the direct products  $\Lambda_i \times \Lambda_j$  ( $i, j = 4, 5, 6$ ) must contain either  $\Lambda_1$  or  $\Lambda_3$ . From Table A4-5, the allowed transitions are:

$$\left. \begin{array}{l}
 \Lambda_4 \longrightarrow \Lambda_5 \\
 \Lambda_4 \longrightarrow \Lambda_6 \\
 \Lambda_5 \longrightarrow \Lambda_6 \\
 \Lambda_6 \longrightarrow \Lambda_6
 \end{array} \right\} \text{ allowed}$$

and

$$\begin{array}{l}
 \Lambda_4 \longrightarrow \Lambda_4 \\
 \Lambda_5 \longrightarrow \Lambda_5
 \end{array} \text{ forbidden}$$

Note that in the absence of a magnetic field,  $\Lambda_4$  and  $\Lambda_5$  are degenerate bands. Therefore, in this case all direct transitions between bands with distinct eigenvalues are possible.

at L.

The symmetries of bands with distinct energies are  $L_4^+$  (or  $L_5^+$ ) and  $L_6^+$ . Since the direct products  $L_6^+ \times L_6^+$ ,  $L_4^+ \times L_6^+$  and  $L_5^+ \times L_6^+$  all contain  $L_3'$ , every transition between distinct states of opposite parity is allowed.

In order to see more clearly how the addition of spin-orbit coupling changes some of the selection rules for direct transitions, we study a particular case in detail: the transition  $\Sigma_3 \longrightarrow \Sigma_4$ . As we have seen, without spin this transition is forbidden; with spin-orbit coupling the transition is allowed. For simplicity, in this example, we ignore all other bands.

Let the unperturbed (spin-independent) Hamiltonian be  $H^{(0)}$  with eigenfunctions  $\psi_3^{(0)}$  and  $\psi_4^{(0)}$  (transforming like  $\Sigma_3$  and  $\Sigma_4$ , respectively) and eigenvalues  $\epsilon_3^{(0)}$  and  $\epsilon_4^{(0)}$ . Call the eigenfunctions under

the double group  $\psi_3^{(0)}$  and  $\psi_4^{(0)}$  before the spin-orbit perturbation is introduced (note that there are really two eigenfunctions for each band, but because each band is doubly degenerate we only use one function for each band). When spin-orbit coupling is added to the Hamiltonian, we find that the diagonal matrix elements  $\langle \psi_i^{(0)} | H_{SO} | \psi_i^{(0)} \rangle$  vanish (proven in Chapter III), and the off diagonal elements  $\langle \psi_i^{(0)} | H_{SO} | \psi_j^{(0)} \rangle$  are proportional to a spin orbit parameter  $\lambda$ . For  $|\epsilon_3^{(0)} - \epsilon_4^{(0)}| \gg \lambda$ , the energies of the bands will be:

$$\epsilon_3 \approx \epsilon_3^{(0)} - \frac{\lambda^2}{\epsilon_3^{(0)} - \epsilon_4^{(0)}}$$

$$\epsilon_4 \approx \epsilon_4^{(0)} + \frac{\lambda^2}{\epsilon_3^{(0)} - \epsilon_4^{(0)}}$$

and the wave functions become (to first order in  $\lambda$ ):

$$\psi_3 = \psi_3^{(0)} + \frac{\lambda}{\epsilon_3^{(0)} - \epsilon_4^{(0)}} \psi_4^{(0)}$$

$$\psi_4 = \psi_4^{(0)} + \frac{\lambda}{\epsilon_4^{(0)} - \epsilon_3^{(0)}} \psi_3^{(0)}$$

The matrix element for a direct transition from band three to band four is

$$\begin{aligned} H'_{34} &= \langle \psi_4 | H' | \psi_3 \rangle \\ &= \frac{\lambda}{\epsilon_4^{(0)} - \epsilon_3^{(0)}} \left[ \langle \psi_3^{(0)} | H' | \psi_3^{(0)} \rangle - \langle \psi_4^{(0)} | H' | \psi_4^{(0)} \rangle \right] \end{aligned}$$

since the matrix elements  $\langle \psi_3^{(0)} | H' | \psi_4^{(0)} \rangle$  vanish by symmetry. Thus the transition probability for the transition will be proportional to

$$\left( \frac{\lambda}{\epsilon_3^{(0)} - \epsilon_4^{(0)}} \right)^2 \quad \text{and therefore the corresponding intensity will}$$

be much less than that of a transition allowed without spin (assuming that the density of states is the same).

(b) Indirect Transitions with Spin

Since the addition of spin in the Hamiltonian serves to bring about more mixing of the unperturbed functions, the matrix elements for the electron-phonon interaction can only increase when spin is added. Because all such interactions were permissible without spin, the transitions are still allowed. In fact, the arguments that were given for the spin-independent situation may be applied here without any changes.

### Appendix Five - Use of Projection Operators to Classify Spin Eigenstates

As mentioned in Chapter III, at the point  $L_3$  the spin-orbit matrix is:

$$H_{so} = \begin{bmatrix} 0 & i & 0 & \sqrt{2}\omega \\ -i & 0 & -\sqrt{2}\omega & 0 \\ 0 & -\sqrt{2}\omega^* & 0 & -i \\ \sqrt{2}\omega^* & 0 & i & 0 \end{bmatrix} \quad (A5-1)$$

$$\text{Where } \omega = e^{i\frac{\pi}{4}}$$

This matrix has four eigenvalues:  $\lambda, \lambda, -\lambda, -\lambda$ . One pair of these eigenvalues must correspond to the degenerate states  $L_4^+$  and  $L_5^+$ ; the other pair is associated with the doubly degenerate state  $L_6^+$ .

One could determine the eigenvectors for these states by applying projection operators to the four functions

( $\psi_1 = \varphi_{1\alpha}, \psi_2 = \varphi_{2\alpha}, \psi_3 = \varphi_{1\beta}, \psi_4 = \varphi_{2\beta}$ ) that form a basis for the product representation of space and spin at L. However, it is unnecessary to use projection operators for all three states  $L_4^+, L_5^+,$  and  $L_6^+$  because once the eigenvalue for any one state, say  $L_4^+$ , is determined, the eigenvalues for the other two states are known.

A projection operator for the  $\alpha^{\text{th}}$  irreducible representation is defined as:

$$P_{ij}^{(\alpha)} = \sum_R \left[ \Gamma_{ij}(R) \right]^*_R \quad (A5-2)$$

here the summation is over the elements R in the group, and  $i, j = 1, \dots, n_\alpha$

where  $n_\alpha$  = dimension of the  $\alpha^{\text{th}}$  irreducible representation.

Thus, for a given value of  $j$ , the  $n_\alpha$  functions  $P_{ij}^{(\alpha)} \psi$  (where  $\psi$  is any arbitrary function) transform as a basis set for the  $\alpha^{\text{th}}$  irreducible representation of the group.

The double group at L (group  $D_{3d}$ ) contains  $2 \times 12 = 24$  operations. Six of these operations are  $R_1, R_5, R_9, R_{19}, R_{21},$  and  $R_{23}$  (see Appendix Three). To each of these operations we add the inversion, which makes a total of twelve operations. Finally, because of spin, to each of these twelve operations, we apply an additional rotation of  $2\pi$  which gives us a final total of 24 operations in all.

Now let us determine the projection operator for the representation  $L_4^+$ . Since this is a one dimensional representation the projection operator applied to a function,  $\psi$ , is

$$P\psi = \sum_R \chi^*(R)R\psi$$

But  $L_4^+$  is even on inversion, so that adding this operation gives nothing new. Similarly, because spinors and the characters of the double-valued representations go into their negative upon rotations through  $2\pi$ , these additional twelve operations may be ignored. Thus the final form of the projection operator for  $L_4^+$  is

$$(A5-3) \quad P = \sum_R \chi^*(R)R \quad (\text{sum on only six elements: } R_1, R_5, R_9, R_{19}, R_{21}, R_{23})$$

The characters  $\chi(R)$  for the representation  $L_4^+$  are:

	$R_1$	$R_5$	$R_9$	$R_{19}$	$R_{21}$	$R_{23}$
$L_4^+$	1	-1	-1	i	i	i

$$\chi(JR_i) = \chi(R_i) \quad J = \text{inversion}$$

$$\chi(\bar{R}_i) = -\chi(R_i)$$

To determine the effect of an operation on a spinor we use the matrices found by Slater.<sup>14</sup> The matrices for the spatial functions are generated by the APW wave functions at  $L_3$ . These matrices are given in Table A5-1.

TABLE A5-1

Basis functions for spinor operations are  $S_1 = \alpha$ ,  $S_2 = \beta$ .

Basis functions for spatial operations are the APW functions  $\varphi_1$  and  $\varphi_2$  at  $L_3$ .

	Spinor Matrices	Spatial Matrices
$R_1$	$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$	$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$
$R_5$	$\begin{pmatrix} \frac{\omega^*}{\sqrt{2}} & \frac{-\omega}{\sqrt{2}} \\ \frac{\omega^*}{\sqrt{2}} & \frac{\omega}{\sqrt{2}} \end{pmatrix}$	$\begin{pmatrix} \frac{-1}{2} & \frac{\sqrt{3}}{2} \\ \frac{-\sqrt{3}}{2} & -\frac{1}{2} \end{pmatrix}$
$R_9$	$\begin{pmatrix} \frac{\omega}{\sqrt{2}} & \frac{\omega}{\sqrt{2}} \\ \frac{-\omega^*}{\sqrt{2}} & \frac{\omega^*}{\sqrt{2}} \end{pmatrix}$	$\begin{pmatrix} \frac{-1}{2} & \frac{-\sqrt{3}}{2} \\ \frac{\sqrt{3}}{2} & -\frac{1}{2} \end{pmatrix}$
$R_{19}$	$\begin{pmatrix} \frac{-i}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\ \frac{-1}{\sqrt{2}} & \frac{i}{\sqrt{2}} \end{pmatrix}$	$\begin{pmatrix} \frac{1}{2} & \frac{-\sqrt{3}}{2} \\ \frac{-\sqrt{3}}{2} & -\frac{1}{2} \end{pmatrix}$
$R_{21}$	$\begin{pmatrix} \frac{i}{2} & \frac{-i}{\sqrt{2}} \\ \frac{i}{\sqrt{2}} & \frac{-i}{\sqrt{2}} \end{pmatrix}$	$\begin{pmatrix} \frac{1}{2} & \frac{\sqrt{3}}{2} \\ \frac{\sqrt{3}}{2} & -\frac{1}{2} \end{pmatrix}$
$R_{23}$	$\begin{pmatrix} 0 & -\omega^* \\ \omega & 0 \end{pmatrix}$	$\begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}$

where  $\omega = e^{i \pi/4}$

The matrices in Table A5-1 are defined by

$$Rf_i = \sum_j \Gamma_{ji}(R) f_j \text{ where } f_i = i^{\text{th}} \text{ basis function}$$

For example, consider operation  $R_5$ :

Spinors

$$R_5\alpha = \frac{\omega^*}{\sqrt{2}} \alpha + \frac{\omega^*}{\sqrt{2}} \beta$$

$$R_5\beta = \frac{-\omega}{\sqrt{2}} \alpha + \frac{\omega}{\sqrt{2}} \beta$$

Space

$$R_5\varphi_1 = -\frac{1}{2} \varphi_1 - \frac{\sqrt{3}}{2} \varphi_2$$

$$R_5\varphi_2 = \frac{\sqrt{3}}{2} \varphi_1 - \frac{1}{2} \varphi_2$$

thus

$$R_5(\varphi_1 \alpha) = (R_5\varphi_1) \cdot (R_5 \alpha)$$

$$= \left(-\frac{1}{2} \varphi_1 - \frac{\sqrt{3}}{2} \varphi_2\right) \cdot \left(\frac{\omega^*}{\sqrt{2}} \alpha + \frac{\omega^*}{\sqrt{2}} \beta\right)$$

$$= \frac{-\omega^*}{2\sqrt{2}} \varphi_1 \alpha - \frac{\sqrt{3}}{2\sqrt{2}} \varphi_2 \alpha + \frac{-\omega^*}{2\sqrt{2}} \varphi_1 \beta - \frac{\sqrt{3}}{2\sqrt{2}} \omega^* \varphi_2 \beta$$

After performing these calculations for all six operations, and using equation A5-3 with the character table for  $L_4^+$ , we find that

$$P(\mathcal{P}_{1\alpha}) = P\psi_1 = \frac{3}{2} \psi_1 + b\psi_2 - \frac{3}{2} \omega^* \psi_3 + b\omega^* \psi_4 = \underline{\Psi}$$

$$P(\mathcal{P}_{2\alpha}) = P\psi_2 = \frac{3}{2} b^* \underline{\Psi}$$

$$P(\mathcal{P}_{1\beta}) = P\psi_3 = -\omega \underline{\Psi}$$

$$P(\mathcal{P}_{2\beta}) = P\psi_4 = b^* \underline{\Psi}$$

$$\text{where } b = \sqrt{\frac{3}{2}} - \sqrt{\frac{3}{2}} i$$

Thus, application of the projection operator for  $L_4^+$  on any of our original functions  $\psi_1, \psi_2, \psi_3, \psi_4$  gives us only one new function (within a constant factor). This is because the irreducible representation  $L_4^+$  is one dimensional. The column vector corresponding to  $\underline{\Psi}$

$$\begin{pmatrix} 3/2 \\ b \\ -3/2 \\ b\omega^* \end{pmatrix} \omega^*$$

is an eigenvector of the spin orbit matrix (equation A5-1) with eigenvalue  $+\lambda$ . Since  $L_4^+$  and  $L_5^+$  are degenerate by time reversal,  $L_5^+$  also has energy  $+\lambda$ . Consequently the doubly degenerate state  $L_6^+$  has energy  $-\lambda$ .

As a check on our results, we can apply the time reversal operator

$$K = -i \sigma_y K_0$$

$$\text{where } \sigma_y = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}$$

$K_0 = \text{complex conjugation}$

to our eigenfunction for  $L_4^+$ . The new function  $K\bar{\Psi}$  is the eigenfunction for  $L_5^+$ . We find that

$$K \bar{\Psi} = \begin{pmatrix} \frac{3}{2} \omega \\ -b^* \omega \\ \frac{3}{2} \\ b^* \end{pmatrix}$$

is an eigenvector of the spin-orbit matrix with eigenvalue  $+\lambda$  as required. We also verify that  $\bar{\Psi}$  and  $K\bar{\Psi}$  are orthogonal since they transform as basis functions for different irreducible representations:

$$(\bar{\Psi}, K\bar{\Psi}) = \left[ \frac{3}{2}, b^*, -\frac{3}{2} \omega^*, b^* \omega \right] \begin{pmatrix} \frac{3}{2} \omega \\ -b^* \omega \\ \frac{3}{2} \\ b^* \end{pmatrix} = \frac{9}{4} \omega - b^{*2} \omega - \frac{9}{4} \omega + b^{*2} \omega = 0$$

Biographical Sketch

The author was born at Lakewood, New Jersey on March 8, 1938. He attended the public schools there, graduating from Lakewood High School in June of 1955. He majored in physics at M. I. T. and received the degree of Bachelor of Science in June of 1959. In the Fall of 1959 he entered the Graduate School of M. I. T. and began his graduate study.
