## BIOGRAPHICAL SKETCH

The author was born in Budapest, Hungary on December 28, 1929. After finishing high school, he attended the Hungarian Institute of Technology for a short while before emigrating to the United States in 1948. He went to his parents and brother in Dayton, Ohio, where he attended the University of Dayton. In 1949 he entered the University of Cincinnati in Ohio, where he graduated in 1954 as the outstanding engineering senior, receiving the degree of Mechanical Engineer. In August of 1954 he married Elizabeth Owens, also a graduate of the University of Cincinnati and a Canadian by birth. They then moved to the University of Illinois where the author held a Visking Corporation Fellowship. In 1955 he received the Master of Science degree there. The same year they came to M.I.T. to accept a Whitney Fellowship. The author started his teaching career as an assistant in 1956. He was promoted to Instructor in 1957 and to Assistant Professor in 1958. During the summers he worked in industry as engineer and consultant. At present their family consists of a daughter, Christine, and a son, David.

Submitted to the Department of Mechanical Engineering on  
May 14, 1960 in partial fulfillment of the requirements  
for the degree of Doctor of Philosophy.

## ABSTRACT

The fluid mechanics and heat transfer phenomena occurring during condensation inside single-pass, horizontal and slightly inclined condenser tubes were investigated analytically and experimentally.

Two independent analyses were developed for the condensate forming on the wall. One was the development of the boundary layer equations for a class of curved surfaces for which similarity solutions exist. These equations could be solved for a circular tube only approximately. The second method was the derivation of approximate solutions from the momentum-energy relations. Both methods yielded similar results indicating that for ordinary refrigerants under normal operating conditions the complete solution does not differ significantly from the simplest approximation which is identical to the one developed by Nusselt. For liquid metals, however, both of these methods indicate a significant reduction of heat transfer rates as compared to the simplified solution. There is a discrepancy between the results of the two methods as to the actual magnitudes; however, the boundary conditions for the second method are more reasonable, and consequently, its results can be considered more reliable.

The momentum equation was developed for the bottom condensate flow and certain depth criteria were established. It was shown that a relatively slight downward inclination will significantly increase the heat transfer rates. Beyond a certain slope, however, heat transfer will be reduced again due to the changing flow pattern of the wall condensate. A simple optimization procedure was developed for determining the slope for the highest heat transfer rate.

A fluid mechanics analogy setup was used with water for the horizontal position, and a condensation apparatus was built for the investigation of both fluid mechanics and heat transfer in horizontal and inclined tubes, using Refrigerant-113. These results check the analyses well within the experimental errors.

Thesis Supervisor: Warren M. Rohsenow

Title: Professor of Mechanical Engineering

## ACKNOWLEDGEMENTS

The author wishes to thank the following people for their help, advice, discussion, or encouragement during this work:

The members of the thesis committee, Professors A. L. Hesselschwerdt, Jr., W. M. Rohsenow, and A. H. Shapiro.

Professor P. Griffith, Messrs. M. M. Chen, and E. M. Dimond.

Miss Alice Seelinger for an excellent typing job.

Last, but not least, my entire family and especially my wife, Beth, whose moral support was indispensable.

The project was sponsored in part by the A.S.R.E., now called A.S.H.R.A.E., and by the Whirlpool Corporation.

The experimental work was done at the MIT Refrigeration and Air Conditioning Laboratories, which are under the direction of Professor A. L. Hesselschwerdt, Jr.

Part of the work was performed at the MIT Computation Center.

## CHAPTER I

### INTRODUCTION

#### Definition of the Problem

The basic mechanism of condensation inside a horizontal tube is the same as that occurring on the outside of a tube; but the geometrical restrictions imposed upon the former make the problem considerably more complex. The easiest way to analyze the process is to follow the "life history" of the medium as it passes through the tube. Thus, the following phenomena can be found as distinct but interrelated phases of the overall picture:

1. The flow of vapor in the tube
2. The mass and heat transfer at the vapor-condensate interface
3. The flow of condensate on the side walls of the tube
4. The heat transfer through this condensate layer
5. The axial flow of the liquid on the bottom of the tube discharging at the outlet
6. The heat transfer through this layer
7. The interactions between these various phenomena.

Each of the above items can be studied separately at first, but it is obvious that the problem has to be solved ultimately by interrelating all of them.

A qualitative examination of the above phenomena immediately reveals that the most profound difference between condensation on the outside and on the inside of a tube results from the simple geometrical

restriction forced upon the latter case. This is that all the vapor to be condensed has to enter at the inlet, while all the liquid condensed in the tube and any vapor to be condensed subsequently has to leave through the outlet. In other words, the total mass flow has to pass through the relatively confined volume created by the tube itself. This condition creates relatively strong interactions between the various phenomena described above which usually do not exist when the vapor condenses on the outside of a tube.

Although in most cases it is more advantageous to condense on the outside of the tube, there are certain applications where condensation on the inside is inherently required. Two outstanding examples of this latter condition are the air cooled condensers, used primarily in air conditioning and refrigeration, and the radiation cooled condensers, employed primarily in vehicles for outer space. These two applications, however, have a very basic difference between them, namely the influence of gravity. For an orbiting space vehicle the terms horizontal and vertical have no real significance and gravity, unless it is artificially created, plays no part at all. In the case of the "earth-bound" condensers, gravity exerts an all important influence on the phenomena occurring. In the following chapters this latter problem will be investigated almost exclusively, first because of its commercial importance and second because of its greater complexity.

The method of investigation will follow essentially the outline given previously; that is, the "life history" of the medium will be traced along the tube. For the purpose of analysis it will be

assumed that film-wise condensation occurs, which is the usual case.

In order to define the problem more precisely, the flow will be investigated primarily for the case of a single pass condenser tube. Thus the end conditions will be that only vapor enters and only condensate leaves the tube. As it will be seen later such a narrowing of the scope is necessary in order to eliminate some variables from a very complex process.

Superheated vapor introduces some problems of physical chemistry not yet fully understood. Consequently this investigation will be restricted to the case of the pure saturated vapor.

### Historical Background

The classical work of Nusselt (37)\* forms the basis of most subsequent analyses of film condensation. A number of investigators elaborated on this theory and used it for comparison to experimental results. An excellent and exhaustive review of references is given by McAdams (34) who also summarizes the experimental results. The measured values of the heat transfer coefficients run from about 36% below to 70% above the predicted values for condensation of pure saturated vapors on the outside of single horizontal tubes.

Until recently the analytical investigations were based essentially on an improvement of the original Nusselt theory. Peck and Reddie (38) included an acceleration term, but their formulation of the equation was incorrect. Bromley, et al (8) investigated the effect of temperature variation around the tube, then Bromley (7) and later Rohsenow (40) examined the problem of subcooling of the condensate and suggested correction factors. These results indicated that for the usual operating conditions all these effects are negligible for pure saturated vapors. Recently Sparrow and Gregg (46,47) presented solutions of boundary-layer type equations developed for the condensate layer. Their results indicate that although for the usual fluids, with relatively high Prandtl Numbers, there is no significant change from the Nusselt solution; the heat transfer rates are significantly lowered for liquid metals with very low Prandtl numbers.

Analysis of the condensation inside horizontal tubes was made by Chaddock (10) who used the Nusselt analysis together with an empirical relation for the depth of the bottom condensate.

---

\* Numbers in parentheses refer to numbers in the Bibliography.

Experimental investigations of condensation inside horizontal, or nearly horizontal, tubes were relatively few until recently. Jakob, et al (26) and Jakob (24, 25) condensed steam and found good agreement with the Nusselt theory even though the effect of the axially flowing bottom condensate was ignored. Trapp (50, 51) found heat transfer coefficients for ammonia and alcohol vapors which were generally lower than the theory predicted. Chaddock's (10) and Dixon's (15) experiments indicated that the variation of the depth of the bottom condensate is small in tubes up to a length-diameter ratio of about 30.

A number of experiments were done with relatively high vapor velocities existing in the tubes. Under such circumstances the vapor shear has greater importance and the results show marked deviation from the Nusselt theory. Tepe and Mueller (49) condensing benzene and methanol inside a tube inclined at  $15^\circ$  from horizontal found coefficients 1.5 times higher than the Nusselt results. Akers, et al (2, 3) correlated a great number of local heat transfer data as a function of a density-corrected local Reynolds Number, and his points fall for the most part above the Nusselt values, particularly at high flow rates. Hakimi's (18) results with Refrigerant 12 agreed well with Akers' correlation and were about 30% above theoretical values. None of these results, however, cover the situation that was to be investigated in this work; namely, where the condensate layer on the bottom is deep enough to seriously influence the heat transfer rates, and the vapor shear is relatively low for most part of a relatively long condenser tube.

Misra and Bonilla (36) did condensation experiments with liquid metals. Their results were markedly below the theoretical values

predicted by any of the analyses and the scatter was very large. This was due primarily to the lack of control of the vapor shear conditions at the interface. Consequently this data is good only for qualitative comparison.

Recent investigations have thrown some light on the phenomenon observed quite a long time ago, among others by Jakob (24), that when superheated vapor is condensed the liquid interface temperature is lower than that corresponding to thermodynamic equilibrium. Schrage (45) did basic analyses on this problem, and Balekjian and Katz (5) used some of his results to correlate their data. This field is still quite unexplored and more investigations will be needed. Until then, heat transfer correlations with superheated vapor have to be treated very carefully.

The problem of condensation on an inclined tube was investigated by Hassan and Jakob (19), who found analytically that for a long tube the heat transfer rate varies as the one-fourth power of the cosine of the inclination.

## CHAPTER II

## THE VAPOR PHASE

In the usual case where the specific volume of the vapor is considerably greater than that of the liquid, the medium enters at a relatively high velocity. As more and more is condensed along the tube, the vapor slows down. In the case of single-pass condenser tubes the vapor velocity becomes essentially zero at the outlet end. It is clear that both entrance and exit conditions have to be considered for the complete definition of the problem. The most profound aspects of such a process as condensation inside a tube are that there is no fully developed flow, it is constantly changing spatially; and that the flow cannot get far enough from end effects to escape their influence. As a matter of fact end effects exert all important control on the entire process.

Since in a horizontal tube condensate collects at the bottom, the cross-section of the vapor flow is asymmetric. There is not much information available on such flows. Analyses are practically nonexistent and experimental data are rather scarce. The most complete and detailed work is that of Gazley (16) whose experiments were done on two-phase mixtures without change of phase. For lack of better information it may be assumed that the friction factors found in this reference can be applied to the constantly varying vapor flow in a condenser tube. In the horizontal tube the flow pattern is further complicated by the fact that, with the exception of the very lowest of flow rates, there are always surface waves generated on the bottom condensate. In the confined space available these waves have very

pronounced effect on the vapor flow. In particular, they increase the energy loss from the flow and, correspondingly, cause a greater pressure drop. The asymmetric configuration and the surface waves generated on the bottom condensate indicate that the equivalent friction losses are not uniformly distributed around the circumference of the flow.

Compared to the wavy surface of the bottom condensate, the liquid on the walls is smooth if the condensation is film-wise, as is the usual case. Consequently, the friction losses at the wall are probably lower than at the bottom of the tube. If the tube is inclined, most of these surface waves disappear and the friction losses become more uniform around the periphery. For the purpose of calculations the concept of friction factor will be used with the numerical values taken primarily from Gazley's (16) data.

As was mentioned earlier, there is a rather important difference between the condensation of a saturated vapor and that of a superheated vapor. In the former case the surface of the condensate in contact with the vapor may be considered to be very nearly in thermodynamic equilibrium with the vapor; that is, the temperature of this surface may be taken as the saturation temperature, the same as that of the vapor. Thus, essentially no heat transfer occurs in the vapor. However, there is a slow outward movement towards the condensing surfaces. Under such circumstances it is reasonable to consider the vapor as uniform in temperature and in pressure at any cross-section; and, if the pressure drop is small along the tube, temperatures may be taken as uniform everywhere in the vapor phase.

If the vapor entering the tube is superheated, then the entire condensation process becomes much more complicated. Some of the most

important effects arising from this condition have been observed and discussed by several investigators (5, 24, 45). The first and most obvious difference is that the vapor has to be cooled before it can condense. Consequently, a temperature gradient exists in the core of the tube which depends not only on the amount of superheat, but also on the magnitude of the subcooling of the condensate. The peculiarities of this dependence have been observed and discussed by Jakob (5), who found that, as the subcooling increased, the temperature of the core of the vapor became higher at the outlet end instead of lower. He explained this observation by pointing out that at higher subcooling, the vapor-liquid interface is at a lower temperature; and, consequently, any vapor molecule hitting the surface will have a much greater tendency to condense instead of returning to the core. At lower subcooling greater number of molecules can approach the interface, then return to the vapor core at a lower temperature level and cause an overall reduction of the vapor temperature. Another important effect of superheat occurs at and near the interface. Thermodynamic equilibrium does not exist anymore, and the condensate surface temperature is different from that of saturation. As it was mentioned above, the condensate is sub-cooled, and the surface temperature is also lowered. To the author's knowledge the correlation of Balekjian and Katz (5), based on some of Schrage's work (45), is the best available on this phenomenon.

Data in this investigation were all taken with saturated vapor, therefore, the effect of superheat did not appear.

## CHAPTER III

## CONDENSATION ON THE TUBE WALLS

The Momentum-Energy Equation

A solution to the problem of condensation on an inclined surface may be obtained by writing the momentum and energy equations for the condensate flow. By using the concept of similarity, these equations may be reduced to a single ordinary differential equation with only one dependent and one independent variable\*.

Consider the flow of condensate along the surface in the positive  $x$  direction as shown in Figure 3.1. At some position  $x$ , the condensate film thickness is  $y_s$ . The momentum equation in the  $x$  direction can be written as follows.

$$\frac{d}{dx} \int_0^{y_s} \rho_l u^2 dy + \frac{d}{dx} \int_{y_s}^{y_\infty} \rho_v u^2 dy + \mu_l \left. \frac{\partial u}{\partial y} \right|_w = y_s g (\rho_l - \rho_v) \sin \phi \quad (3.1)$$

where  $x$  distance along plate, ft.

$y$  distance perpendicular to plate into the fluid, ft.

$\rho_l$  liquid mass density, slugs/ft<sup>3</sup>

$\rho_v$  vapor mass density, slugs/ft<sup>3</sup>

$u$  velocity in  $x$  direction, ft/sec

$\mu_l$  liquid viscosity, lbf-sec/ft<sup>2</sup>

$g$  gravitational acceleration, ft/sec<sup>2</sup>

$\phi$  surface inclination to horizontal

---

\* This approach is due to Mr. Michael M. Chen.

The energy equation becomes,

$$-k_e \frac{\partial t}{\partial y} \Big|_w = -\frac{d}{dx} \int_0^{y_s} \lambda \rho_l u \, dy - \frac{d}{dx} \int_0^{y_s} c_{pl} (t_s - t) \rho_l u \, dy \quad (3.2)$$

where  $k_e$  thermal conductivity of liquid, Btu/sec-ft-°F

$t$  temperature, °F

$t_s$  temperature at the liquid-vapor interface,  $y_s$ , °F

$\lambda$  latent heat of vaporization, Btu/slug

$c_{pl}$  specific heat of liquid, Btu/slug-°F

To non-dimensionalize the above equations, define the following quantities as special properties of the velocity and temperature profiles.

$$u_a \equiv \frac{1}{y_s} \int_0^{y_s} u \, dy$$

$$\Delta t \equiv t_s - t_w$$

where  $t_w$  is wall temperature

$$y^+ \equiv \frac{y}{y_s}$$

$$u^+ \equiv \frac{u}{u_a}$$

$$t^+ \equiv \frac{t - t_w}{\Delta t}$$

$$R \equiv \frac{\partial u^+}{\partial y^+} \Big|_w$$

$$B \equiv \int_0^1 u^{+2} \, dy^+$$

$$C \equiv \int_0^1 u^+ (1 - t^+) dy^+ = 1 - \int_0^1 u^+ t^+ dy^+$$

$$D \equiv \left. \frac{\partial t^+}{\partial y^+} \right|_w$$

Substituting these relations into the momentum equation (3.1) and ignoring the contribution of the vapor phase, since  $\rho_v \ll \rho_l$  for ordinary applications, yields\*,

$$\frac{d}{dx} \rho_l u_a^2 y_s B + \mu_l \frac{u_a}{y_s} F = y_s g (\rho_l - \rho_v) \sin \phi \quad (3.3)$$

Similarly the energy equation (3.2) becomes,

$$k_l \frac{\Delta t}{y_s} D = \frac{d}{dx} \lambda \rho_l u_a y_s + \frac{d}{dx} c_{pl} \Delta t \rho_l u_a y_s C \quad (3.4)$$

Define,  $f \equiv u_a y_s$ , the volumetric liquid flow rate per unit length of tube, and  $S \equiv \frac{c_{pl} \Delta t}{\lambda}$ .

Thus equation (3.4) becomes,

$$\begin{aligned} k_l \frac{\Delta t}{y_s} D &= \frac{d}{dx} \lambda \rho_l f + \frac{d}{dx} \lambda S \rho_l f C \\ &= \frac{d}{dx} \lambda \rho_l f (1 + CS) \end{aligned} \quad (3.5)$$

---

\* It is shown in the appendix that this can be done provided

$$\frac{\rho_v \mu_v}{\rho_l \mu_l} \ll 1$$

If there is a similarity solution to these equations, then the functions of the velocity and temperature profiles, A, B, C, D, are independent of x. If, in addition, the temperature remains constant along the wall, the equations may be reduced to a single ordinary differential equation in the following manner.

From equation (3.5),

$$\frac{1}{y_s} = \frac{\rho_e \lambda (1 + C_S)}{k_e \Delta t D} \cdot \frac{df}{dx}$$

$$y_s = \frac{k_e \Delta t D}{\rho_e \lambda (1 + C_S) \frac{df}{dx}} \quad (3.6)$$

$$\frac{dy_s}{dx} = - \frac{k_e \Delta t D}{\rho_e \lambda (1 + C_S)} \cdot \frac{\frac{d^2 f}{dx^2}}{\left(\frac{df}{dx}\right)^2} \quad (3.7)$$

Multiplying equation (3.3) by  $y_s / \mu_e u_a A$  and using equations (3.6) and (3.7) together with the definition of f yields,

$$\frac{B \rho_e y_s}{A \mu_e u_a} \left[ 2 u_a y_s \frac{du_a}{dx} + u_a^2 \frac{dy_s}{dx} \right] + 1 = \frac{g (\rho_e - \rho_w) y_s^2 \sin \phi}{A \mu_e u_a}$$

$$\frac{B \rho_e}{A \mu_e} \left[ 2 y_s \frac{df}{dx} - f \frac{dy_s}{dx} \right] + 1 = \frac{g (\rho_e - \rho_w) y_s^3 \sin \phi}{A \mu_e u_a y_s}$$

$$\frac{BDk_e\Delta t}{R\mu_e\lambda(1+C_S)} \left[ 2 + \frac{f \frac{d^2f}{dx^2}}{\left(\frac{df}{dx}\right)^2} \right] + 1 =$$

$$\left[ \frac{k_e\Delta t D}{\rho_e\lambda(1+C_S)} \right]^3 \cdot \frac{g(\rho_e - \rho_0) \sin\phi}{R\mu_e f \left(\frac{df}{dx}\right)^3} \quad (3.8)$$

Define a dimensionless flow rate and distance as follows,

$$F \equiv f \left[ \frac{D^3 g(\rho_e - \rho_0) k_e^3 \Delta t^3 \ell^3}{R\mu_e \rho_e^3 \lambda^3 (1+C_S)^3} \right]^{-\frac{1}{4}} \quad (3.9)$$

where  $\ell$  is a characteristic length.

$$X \equiv \frac{x}{\ell}, \quad F' \equiv \frac{dF}{dX}$$

Thus equation (3.8) becomes,

$$1 - \frac{\sin\phi}{F(F')^3} = - \frac{BDk_e\Delta t}{R\mu_e\lambda(1+C_S)} \left[ 2 + \frac{FF''}{(F')^2} \right] \quad \text{or} \quad (3.10)$$

$$1 - \frac{\sin\phi}{F(F')^3} = -\epsilon \left[ 2 + \frac{FF''}{(F')^2} \right] \quad (3.10a)$$

The right hand side of the equation represents the effect of momentum. The results of Nusselt's analysis indicate that this effect is small.

Thus the right hand side of the equation may be considered as a small perturbation term, and the complete equation may be solved by successive approximations.

The heat transfer coefficient may be computed by considering the heat transferred at the wall.

$$h_m \Delta t = k_e \left. \frac{\partial t}{\partial y} \right|_w = D k_e \frac{\Delta t}{y_s}$$

where  $h_m$  - heat transfer coefficient

$$\begin{aligned} h_m &= \frac{D k_e}{y_s} \\ &= \frac{\rho_e \lambda (1 + CS)}{\Delta t} \cdot \frac{df}{dx} \\ &= \left[ \frac{D^3 g \rho_e (\rho_e - \rho_w) k_e^3 \lambda (1 + CS)}{A \mu_e l \Delta t} \right]^{\frac{1}{4}} F' \end{aligned} \quad (3.11)$$

The local Nusselt number is

$$\begin{aligned} Nu &= \frac{h_m l}{k_e} = \left[ \frac{D^3 g \rho_e (\rho_e - \rho_w) \lambda (1 + CS) l^3}{A \mu_e k_e \Delta t} \right]^{\frac{1}{4}} F' \\ &= \left[ \frac{D^3 (1 + CS)}{A} \right]^{\frac{1}{4}} \left[ \frac{g \rho_e (\rho_e - \rho_w) l^3 \lambda}{\mu_e k_e \Delta t} \right]^{\frac{1}{4}} F' \end{aligned} \quad (3.12)$$

The mean Nusselt number becomes,

$$\overline{Nu} = \left[ \frac{D^3 (1 + CS)}{A} \right]^{\frac{1}{4}} \left[ \frac{g \rho_e (\rho_e - \rho_w) l^3 \lambda}{\mu_e k_e \Delta t} \right]^{\frac{1}{4}} \frac{F}{X} \quad (3.13)$$

Application of the Momentum-Energy Equation to a Round Horizontal Tube

First Approximation

For condensation on a horizontal tube define  $l \equiv r_0$ , the radius of the condensing surface, in the equations. If the condensate film thickness is very much smaller than  $r$ , the previously derived equations may be applied. From equation (3.10a)

$$F(F')^3 - \sin \phi = -\epsilon \left[ 2F(F')^3 + F^2 F' F'' \right] \quad (3.14)$$

The boundary condition is,  $F = 0$  at  $\phi = 0$  at the top of the tube.

Express  $F$  in polynomial form.

$$F = F_0 + F_1 \epsilon + F_2 \epsilon^2 + \dots \quad (3.15)$$

where  $\epsilon$  was defined in equation (3.10a).

$F_0$  may be found by letting  $\epsilon$  approach zero.

$$F_0 (F_0')^3 - \sin \phi = 0 \quad (3.16)$$

Therefore,

$$F_0 = \left( \frac{4}{3} \right)^{\frac{3}{4}} \left[ \int_0^\phi \sin^{1/3} \phi \, d\phi \right]^{\frac{3}{4}} \quad (3.17)$$

The function  $\left[ \int_0^\phi \sin^{1/3} \phi \, d\phi \right]^{\frac{3}{4}}$  is tabulated in Appendix VI.

Substituting into equation (3.13) yields the first approximation of the Nusselt number for a round tube as a function of the distance or angle from the topmost point.

$$\overline{Nu}_o = \left(\frac{4}{3}\right)^{\frac{3}{4}} \left[ \frac{D^3(1+CS)}{A} \right]^{\frac{1}{4}} \left[ \frac{g\rho_e(\rho_e-\rho_v)\lambda r_o^3}{\mu_o k_e \Delta t} \right]^{\frac{1}{4}} \times \frac{\left[ \int_0^\phi \sin^{1/3} \phi \, d\phi \right]^{\frac{3}{4}}}{\phi} \quad (3.18)$$

If the Nusselt number is to be based on the total area of the tube and not only on the part where condensation actually occurs, the above equation has to be multiplied by  $\phi/\pi$ .

$$\overline{Nu}_o = \left(\frac{4}{3}\right)^{\frac{3}{4}} \left[ \frac{D^3(1+CS)}{A} \right]^{\frac{1}{4}} \left[ \frac{g\rho_e(\rho_e-\rho_v)\lambda r_o^3}{\mu_o k_e \Delta t} \right]^{\frac{1}{4}} \times \frac{\left[ \int_0^\phi \sin^{1/3} \phi \, d\phi \right]^{\frac{3}{4}}}{\pi} \quad (3.19)$$

As a first approximation, Nusselt's parabolic velocity and linear temperature distributions may be used. That is,

$$u^+ = 3y^+ - \frac{3}{2}y^{+2} \quad (3.20)$$

$$t^+ = y^+ \quad (3.21)$$

Then  $A = 3$ ,  $B = 6/5$ ,  $C = 3/8$ , and  $D = 1$ . The mean Nusselt number then becomes,

$$\overline{Nu}_0 = \frac{(4)^{\frac{3}{4}}}{3\pi} \left(1 + \frac{3}{8} S\right)^{\frac{1}{4}} \left[ \frac{g\rho_e(\rho_e - \rho_\infty)\lambda r_0^3}{\mu_e k_e \Delta t} \right]^{\frac{1}{4}} \left[ \int_0^\phi \sin^{\frac{1}{3}} \phi \, d\phi \right] \quad (3.22)$$

Since  $S$  is usually very small, the equation may be expressed in a more convenient form as follows.

$$\overline{Nu}_0 = 0.300 \left[ \frac{g\rho_e(\rho_e - \rho_\infty)\lambda \left(1 + \frac{3}{8} S\right) r_0^3}{\mu_e k_e \Delta t} \right]^{\frac{1}{4}} \left[ \int_0^\phi \sin^{\frac{1}{3}} \phi \, d\phi \right]^{\frac{3}{4}} \quad (3.23)$$

For small values of  $S$ , the numerical results of the above equation are identical to those obtained by the Nusselt analysis. The effect of  $S$  and the Prandtl number may be found by successively evaluating the higher order terms in equation (3.15) and by refining the velocity and temperature profiles.

#### Second Approximation

To find  $F_1$ , substitute the first two terms of equation (3.15) into the left hand side of equation (3.14).

$$(F_0 + \epsilon F_1)(F_0' + \epsilon F_1')^3 - \sin \phi = -\epsilon \left[ 2F_0(F_0')^3 + F_0^2 F_0' F_0'' \right] \quad (3.24)$$

If the terms containing  $\epsilon^2$  and  $\epsilon^3$  are neglected, the equation reduces to,

$$3F_0(F_0')^2 F_1' + (F_0')^3 F_1 = -[2F_0(F_0')^3 + F_0^2 F_0' F_0''] \quad (3.25)$$

Equation (3.25) can be solved explicitly for  $F_1$  as follows,

$$[F_0(F_0')^3]^{\frac{2}{3}} [3F_0^{\frac{1}{3}} F_1' + F_0^{-\frac{2}{3}} F_0' F_1] = -[2F_0(F_0')^3 + F_0^2 F_0' F_0'']$$

$$\sin^{2/3} \phi \frac{d}{d\phi} [3F_0^{\frac{1}{3}} F_1] = -\sin \phi \left[ 2 + \frac{F_0 F_0''}{(F_0')^2} \right]$$

$$F_0^{\frac{1}{3}} F_1 = -\frac{2}{3} \int_0^{\phi} \sin^{1/3} \phi \, d\phi - \frac{1}{3} \int_0^{\phi} \frac{F_0 F_0''}{(F_0')^2} \sin^{1/3} \phi \, d\phi$$

Substituting the values of  $F_0$ ,  $F_0'$ , and  $F_0''$  from equation (3.17) and simplifying yields,

$$F_0^{\frac{1}{3}} F_1 = -\frac{F_0^{\frac{4}{3}}}{2} + \frac{1}{9} \int_0^{\phi} \left[ \sin^{1/3} \phi - \frac{4}{3} \cot \phi \int_0^{\phi} \sin^{1/3} \phi \, d\phi \right] d\phi$$

Defining,

$$I_1 = \frac{\frac{4}{3} \int_0^{\phi} \sin^{1/3} \phi \, d\phi}{\sin^{4/3} \phi} \quad (3.26)$$

and substituting gives,

$$F_1 = -\frac{5}{12} F_0 - \frac{F_0^{-\frac{1}{3}}}{9} \int_0^\phi I_1 \sin^{1/3} \phi \cos \phi d\phi \quad (3.27)$$

Define,

$$I_2 \equiv \int_0^\phi I_1 \sin^{1/3} \phi \cos \phi d\phi \quad (3.28)$$

Values for this function were obtained graphically.

Equation (3.27) becomes

$$F_1 = -\frac{5}{12} F_0 - \frac{F_0^{-\frac{1}{3}}}{9} I_2 \quad (3.29)$$

With this solution the second approximation of the Nusselt number is

$$\begin{aligned} \overline{Nu}_1 = & \left(\frac{4}{3}\right)^{\frac{3}{4}} \left[ \frac{D^3(1+CS)}{H} \right]^{\frac{1}{4}} \left[ \frac{g\rho_e(\rho_e-\rho_w)\lambda r_0^3}{\mu_e k_e \Delta t} \right]^{\frac{1}{4}} \times \\ & \times \left[ \frac{\int_0^\phi \sin^{1/3} \phi d\phi}{\phi} \right]^{\frac{3}{4}} \left[ 1 - \epsilon \left( \frac{5}{12} + \frac{I_2}{12 \int_0^\phi \sin^{1/3} \phi d\phi} \right) \right] \end{aligned} \quad (3.30)$$

or

$$\begin{aligned} \overline{Nu}_1 = & \frac{1}{\pi} \left(\frac{4}{3}\right)^{\frac{3}{4}} \left[ \frac{D^3(1+CS)}{H} \right]^{\frac{1}{4}} \left[ \frac{g\rho_e(\rho_e-\rho_w)\lambda r_0^3}{\mu_e k_e \Delta t} \right]^{\frac{1}{4}} \times \\ & \times \left[ \int_0^\phi \sin^{1/3} \phi d\phi \right]^{\frac{3}{4}} \left[ 1 - \epsilon \left( \frac{5}{12} + \frac{I_2}{12 \int_0^\phi \sin^{1/3} \phi d\phi} \right) \right] \end{aligned} \quad (3.31)$$

To find improved velocity and temperature profiles, the momentum and energy equations may be solved for a fluid element between  $y$  and  $y_s$ . The momentum equation is,

$$\begin{aligned} \frac{d}{dx} \int_y^{y_s} \rho_e u^2 dy + u \frac{d}{dx} \int_0^y \rho_e u dy + \mu_e \frac{\partial u}{\partial y} - \mu_e \frac{\partial u}{\partial y} \Big|_s - \\ - u_s \frac{d}{dx} \int_0^{y_s} \rho_e u dy = (y_s - y) g(\rho_e - \rho_w) \sin \phi \end{aligned} \quad (3.32)$$

By an order of magnitude estimate of the vapor momentum equation, which is developed in Appendix I, it can be concluded that

$$\mu_e \frac{\partial u}{\partial y} \Big|_s + u_s \frac{d}{dx} \int_0^{y_s} \rho_e u dy \approx \frac{\mu_w \rho_w}{\mu_e \rho_e} \ll 1$$

Consequently, these two terms effectively cancel each other, although individually they are not negligible. Using this relation the momentum equation becomes in non dimensional form,

$$\begin{aligned} \frac{d}{dx} \rho_e u_a^2 y_s \int_{y^+}^1 u^{+2} dy^+ + u_a u^+ \frac{d}{dx} \rho_e u_a y_s \int_0^{y^+} u^+ dy^+ + \\ + \mu_e \frac{u_a}{y_s} \frac{\partial u^+}{\partial y^+} = y_s (1 - y^+) g(\rho_e - \rho_w) \sin \phi \end{aligned}$$

Multiplying by  $y_s / \mu_e u_a$ , and assuming again that the velocity and temperature profiles are independent of  $x$  leads to the following derivation (similarly to equation 3.8),

$$\frac{Dk_e \Delta t}{\mu_e \lambda (1 + C_3)} \left\{ \left[ 2 + \frac{ff''}{(f')^2} \right] \int_{y^+}^1 u^{+2} dy^+ + \right.$$

$$\left. + u^+ \int_0^{y^+} u^+ dy^+ \right\} + \frac{du^+}{dy^+} =$$

$$= \frac{g(\rho_e - \rho_w)}{\mu_e} \left[ \frac{Dk_e \Delta t}{\mu_e \lambda (1 + C_3)} \right]^3 \cdot \frac{\sin \phi}{f(f')^3} (1 - y^+)$$

or

$$\frac{du^+}{dy^+} = A \frac{\sin \phi}{F(F')^3} (1 - y^+) - \frac{Dk_e \Delta t}{\mu_e \lambda (1 + C_3)} \left\{ \left[ 2 + \right. \right.$$

$$\left. + \frac{FF''}{(F')^2} \right] \int_{y^+}^1 u^{+2} dy^+ + u^+ \int_0^{y^+} u^+ dy^+ \left. \right\}$$

$$= A(1 - y^+) - \frac{A}{B} \left\{ \left[ 2 + \frac{FF''}{(F')^2} \right] \left[ -B(1 - y^+) + \right. \right.$$

$$\left. + \int_{y^+}^1 u^{+2} dy^+ \right] + u^+ \int_0^{y^+} u^+ dy^+ \left. \right\}$$

Substituting the definition of B on the right hand side yields

$$\frac{du^+}{dy^+} = A(1-y^+) - \frac{A}{B} \epsilon \left\{ \left[ 2 + \frac{FF''}{(F')^2} \right] \left[ B y^+ + \int_0^{y^+} u^{+2} dy^+ \right] + u^+ \int_0^{y^+} u^+ dy^+ \right\} \quad (3.33)$$

As before, if  $\epsilon$  is small, the equation may be solved by successive evaluation of the terms in the series expansion for  $u^*$  and  $A$ .

$$u^+ = u_0^+ + \epsilon u_1^+ + \dots$$

$$A = A_0 + \epsilon A_1 + \dots$$

Let

$$\frac{\partial u_0^+}{\partial y^+} = A_0(1-y^+)$$

with the boundary condition

$$\int_0^1 u^+ dy^+ = 1$$

therefore,

$$u_0 = 3 \left( y^+ - \frac{1}{2} y^{+2} \right) \quad (3.6)$$

with  $A_0 = 3$ ,  $B_0 = 6/5$ ,  $D_0 = 1$

$$\int_0^{y^+} u_0^{+2} dy^+ = 3 y^{+3} - \frac{9}{4} y^{+4} + \frac{9}{20} y^{+5} \quad (3.34)$$

$$u_0^+ \int_0^{y^+} u_0^+ dy^+ = \frac{9}{2} y^{+3} - \frac{15}{4} y^{+4} + \frac{3}{4} y^{+5} \quad (3.35)$$

Substituting into (3.33) gives the second approximation of the velocity profile.

$$\begin{aligned} \frac{du_i^+}{dy^+} = & A_1(1-y^+) - \frac{5}{2} \left\{ \left[ 2 + \frac{2I_1 \cos \phi}{5} \right] y^+ + \right. \\ & + \left[ \frac{19}{2} + I_1 \cos \phi \right] y^{+3} - \left[ \frac{15}{2} + \frac{3I_1 \cos \phi}{4} \right] y^{+4} + \\ & \left. + \left[ \frac{3}{2} + \frac{3I_1 \cos \phi}{20} \right] y^{+5} \right\} \end{aligned}$$

Integrating,

$$\begin{aligned} u_i^+ = & A_1 \left( y^+ - \frac{1}{2} y^{+2} \right) - \frac{5}{2} \left\{ \left[ 1 + \frac{I_1 \cos \phi}{5} \right] y^{+2} + \right. \\ & + \left[ \frac{19}{8} + \frac{I_1 \cos \phi}{4} \right] y^{+4} - \left[ \frac{3}{2} + \frac{3I_1 \cos \phi}{20} \right] y^{+5} + \\ & \left. + \left[ \frac{1}{4} + \frac{I_1 \cos \phi}{40} \right] y^{+6} \right\} \end{aligned} \quad (3.36)$$

Apply the boundary conditions.

$$\int_0^1 u^+ dy^+ = \int_0^1 (u_0^+ + \epsilon u_1^+ + \dots) dy^+ = 1$$

$$\int_0^1 u_0^+ dy^+ + \epsilon \int_0^1 u_1^+ dy^+ = 1$$

Since the first term is equal to unity,

$$\int_0^1 u_1^+ dy^+ = 0$$

$$\begin{aligned} \frac{1}{3} A_1 - \frac{5}{2} \left\{ \left[ \frac{1}{3} + \frac{I_1 \cos \phi}{15} \right] + \left[ \frac{19}{40} + \frac{I_1 \cos \phi}{20} \right] - \right. \\ \left. - \left[ \frac{1}{4} + \frac{I_1 \cos \phi}{40} \right] + \left[ \frac{1}{28} + \frac{I_1 \cos \phi}{280} \right] \right\} = 0 \end{aligned}$$

$\therefore$

$$A_1 = \frac{499}{112} + \frac{5 I_1 \cos \phi}{7} \quad (3.37)$$

$$\begin{aligned} u_1^+ &= \left[ \frac{499}{112} + \frac{5 I_1 \cos \phi}{7} \right] y^+ - \left[ \frac{1059}{224} + \frac{6 I_1 \cos \phi}{7} \right] y^{+2} - \\ &- \left[ \frac{95}{16} + \frac{5 I_1 \cos \phi}{8} \right] y^{+4} + \left[ \frac{15}{4} + \frac{3 I_1 \cos \phi}{8} \right] y^{+5} - \\ &- \left[ \frac{5}{8} + \frac{I_1 \cos \phi}{16} \right] y^{+6} \\ &= Y_1 y^+ - Y_2 y^{+2} - Y_4 y^{+4} + Y_5 y^{+5} - Y_6 y^{+6} \end{aligned} \quad (3.38)$$

The energy equation becomes,

$$\begin{aligned}
 -k_e \frac{\partial t}{\partial y} = & -\frac{d}{dx} \int_0^{y_s} \lambda \rho_2 u \, dy - \frac{d}{dx} \int_0^{y_s} c_{pe} t_s \rho_2 u \, dy + \\
 & + \frac{d}{dx} c_{pe} t \int_0^y \rho_2 u \, dy + \frac{d}{dx} \int_y^{y_s} c_{pe} t \rho_2 u \, dy
 \end{aligned} \tag{3.39}$$

or in non-dimensional form

$$\begin{aligned}
 k_e \frac{\Delta t}{y_s} \frac{\partial t^+}{\partial y^+} = & \frac{d}{dx} \lambda \rho_2 u_a y_s \int_0^1 u^+ dy^+ + \frac{d}{dx} c_{pe} t_s \rho_2 u_a y_s \int_0^1 u^+ dy^+ - \\
 & - \frac{d}{dx} c_{pe} (\Delta t t^+ + t_w) \rho_2 u_a y_s \int_0^{y^+} u^+ dy^+ - \\
 & - \frac{d}{dx} \rho_2 u_a y_s \int_{y^+}^1 c_{pe} (\Delta t t^+ + t_w) u^+ dy^+ \\
 = & \rho_2 (\lambda + c_{pe} \Delta t) f' - \rho_2 c_{pe} \Delta t f' t^+ \int_0^{y^+} u^+ dy^+ - \rho_2 c_{pe} \Delta t f' \int_{y^+}^1 t^+ u^+ dy^+
 \end{aligned}$$

∴

$$\begin{aligned}
 \frac{\partial t^+}{\partial y^+} = & \frac{y_s \rho_2 (\lambda + c_{pe} \Delta t) f'}{k_e \Delta t} - \frac{y_s \rho_2 c_{pe} f'}{k_e} t^+ \int_0^{y^+} u^+ dy^+ - \\
 & - \frac{y_s \rho_2 c_{pe} f'}{k_e} \int_{y^+}^1 t^+ u^+ dy^+
 \end{aligned} \tag{3.40}$$

Substituting the value of  $y_s$  from equation (3.6),

$$\begin{aligned} \frac{\partial t^+}{\partial y^+} &= D \frac{1+s}{1+Cs} - \frac{Ds}{1+Cs} \left[ t^+ \int_0^{y^+} u^+ dy^+ + \int_{y^+}^1 t^+ u^+ dy^+ \right] \\ &= \frac{Ds}{1+Cs} \left[ \frac{1}{s} + 1 + t^+ \int_0^{y^+} u^+ dy^+ + \int_{y^+}^1 t^+ u^+ dy^+ \right] \end{aligned} \quad (3.41)$$

or,

$$\frac{\partial t^+}{\partial y^+} = D \frac{1+s}{1+Cs} - s \frac{D}{1+Cs} \left[ t^+ \int_0^{y^+} u^+ dy^+ + \int_{y^+}^1 t^+ u^+ dy^+ \right] \quad (3.42)$$

Let

$$t^+ = t_0^+ + s t_1^+ + \dots$$

$$C = C_0 + s C_1 + \dots$$

$$D = D_0 + s D_1 + \dots$$

$$\left. \frac{\partial t_0^+}{\partial y^+} \right|_w = D_0$$

with boundary condition  $t_0^+ = 0$  at  $y^+ = 0$  and  $t_0^+ = 1$  at  $y^+ = 1$

$$t_0^+ = y^+, \quad D_0 = 1, \quad C_0 = \frac{3}{8}$$

Substituting into (3.42) results,

$$\begin{aligned} \frac{\partial t_0^+}{\partial y^+} + s \frac{\partial t_1^+}{\partial y^+} &= \frac{1+sD_1}{1+\frac{3}{8}s} \left\{ 1 + s \left[ 1 - y^+ \int_0^{y^+} 3(y^+ - \frac{1}{2}y^{+2}) dy^+ - \right. \right. \\ &\quad \left. \left. - \int_{y^+}^1 3(y^{+2} - \frac{1}{2}y^{+3}) dy^+ \right] \right\} \\ &= \frac{1+sD_1}{1+\frac{3}{8}s} \left\{ 1 + s \left[ \frac{3}{8} - \frac{1}{2}y^{+3} + \frac{1}{8}y^{+4} \right] \right\} \end{aligned}$$

After integrating and collecting terms

$$t^+ = \frac{1 + 3D_1}{1 + \frac{3}{8}\beta} \left[ \left(1 + \frac{3}{8}\beta\right) y^+ - \beta \left( \frac{1}{8} y^{+4} - \frac{1}{40} y^{+5} \right) \right] \quad (3.43)$$

To satisfy the boundary condition at the interface,  $t_s^+ = 1$ ,

$$1 = \frac{1 + 3D_1}{1 + \frac{3}{8}\beta} \left[ 1 + \frac{3}{8}\beta - \beta \left( \frac{1}{8} - \frac{1}{40} \right) \right]$$

$$D_1 = \frac{1}{10 \left( 1 + \frac{3}{8}\beta \right) - \beta} \quad (3.44)$$

$$t^+ = \frac{1}{1 - \frac{\beta}{10 \left( 1 + \frac{3}{8}\beta \right)}} \left[ y^+ - \frac{\beta}{1 + \frac{3}{8}\beta} \left( \frac{1}{8} y^{+4} - \frac{1}{40} y^{+5} \right) \right] \quad (3.45)$$

This result is identical to the one obtained by Rohsenow (40).

Next find

$$C = 1 - \int_0^1 u^+ t^+ dy^+$$

Substituting from equations (3.6), (3.38), (3.45), and neglecting higher order terms containing  $\epsilon^3$  gives,

$$C = 1 - \int_0^1 \left[ 3(y^+ - \frac{1}{2}y^{+2}) + \epsilon(Y_1 y^+ - Y_2 y^{+2} - Y_4 y^{+4} + Y_5 y^{+5} - Y_6 y^{+6}) \right] \left[ \frac{1}{1 - \frac{3}{10(1 + \frac{3}{8}\epsilon)}} \right] \left[ y^+ - \frac{3}{1 + \frac{3}{8}\epsilon} \left( \frac{1}{8}y^{+4} - \frac{1}{40}y^{+5} \right) \right] dy^+$$

or

$$C = 1 - \frac{3}{1 - \frac{3}{10(1 + \frac{3}{8}\epsilon)}} \left[ \frac{5}{24} - \frac{19}{1920} + \frac{3}{1 + \frac{3}{8}\epsilon} + \epsilon \left( \frac{Y_1}{3} - \frac{Y_2}{4} - \frac{Y_4}{6} + \frac{Y_5}{7} - \frac{Y_6}{8} \right) \right]$$

(3.46)

$$C = 1 - \frac{5}{8 \left[ 1 - \frac{3}{10(1 + \frac{3}{8}\beta)} \right]} + \frac{3}{1 - \frac{3}{10(1 + \frac{3}{8}\beta)} \left[ \frac{3 \times 10^{-2}}{1 + \frac{3}{8}\beta} + \epsilon(0.227 + 0.0346 I, \cos \phi) \right]} \quad (3.47)$$

Using the series expansion form of the constants and substituting equations (3.37) and (3.44) gives the additional quantities to be used in equations (3.30) and (3.31).

$$A = 3 + \epsilon \left( 4.45 + \frac{5 I_1 \cos \phi}{7} \right) \quad (3.48)$$

$$D = 1 + \frac{3}{10 + \frac{11}{4}\beta} \quad (3.49)$$

$$\epsilon = \frac{2 k_e \Delta t}{5 \mu_e \lambda (1 + C\beta)} = \frac{23}{5 (Pr)(1 + C\beta)} \quad (3.50)$$

In the derivation of the basic equation it was assumed that A, B, C, and D are independent of  $\phi$ . From the above equations it is obvious then, that the second approximation is valid only where the terms containing  $\epsilon I$ ,  $\cos \phi$  are small compared to the others.

The results indicate that a small Prandtl number decreases the Nusselt number; while a large Prandtl number tends to increase it slightly. The effect of the Prandtl number as given by this analysis is shown in Figure 3.3. Here the ratio of the Nusselt number obtained from these equations to the number calculated from the original Nusselt analysis (which is essentially the first approximation

described above) is plotted as a function of the temperature difference and the Prandtl number. The angle term containing  $I_2$  was ignored in these calculations since its value is negligible up to an angle of about  $150^\circ$ . For ordinary fluids  $\epsilon$  is usually very small and further approximations are unnecessary. The last approximation already shows that similarity does not exist for a circular tube except at  $\phi = 0$ . The change of the velocity profile is very small up to an angle of about  $150^\circ$ . Based on these observations, Chen (11) concluded that reasonably good approximation may be obtained by assuming that the velocity profile remains similar to the one occurring at  $\phi = 0$ . This means that  $rF''/(F')^2 = 0$ , and equation 3.10a becomes,

$$(1 + \epsilon) F(F')^3 = \sin \phi \quad (3.51)$$

with  $r(0) = 0$ , the solution becomes

$$F = \left(\frac{4}{3}\right)^{\frac{3}{4}} (1 + \epsilon)^{-\frac{1}{4}} \left[ \int_0^\phi \sin^{\frac{1}{3}} \phi \, d\phi \right]^{\frac{3}{4}} \quad (3.52)$$

The velocity profiles now are similar and can be solved by either the perturbation method or by successive substitutions in equation 3.33. The results of this solution are also shown in Figure 3.3 together with the results of Sparrow and Gregg (47) which will be discussed in the next section.

### The Boundary Layer Equations

The problem of film condensation on a surface curved in two dimensions may be approached from the exact Navier-Stokes equations. If it is assumed that the thickness of the condensate layer is much smaller than the radius of curvature at any point, then the equations describing the condensate flow at that point will be the same as that for a flat plate inclined at the same angle to the horizontal. Thus the Navier-Stokes equations may be written in the following form:

$$\frac{\partial u}{\partial \xi} + u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = \frac{g(\rho_l - \rho_v) \sin \phi}{\rho_l} - \frac{1}{\rho_l} \frac{\partial p}{\partial x} + \nu \left( \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right) \quad (3.51)$$

$$\frac{\partial v}{\partial \xi} + u \frac{\partial v}{\partial x} + v \frac{\partial v}{\partial y} = \frac{g(\rho_l - \rho_v) \cos \phi}{\rho_l} - \frac{1}{\rho_l} \frac{\partial p}{\partial y} + \nu \left( \frac{\partial^2 v}{\partial x^2} + \frac{\partial^2 v}{\partial y^2} \right) \quad (3.52)$$

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0 \quad (3.53)$$

The  $x$  direction is along the plate in the downward direction; the  $y$  direction is perpendicularly into the fluid; and  $\phi$  is the downward inclination of the plate to the horizontal as shown in figure 3.1. This notation is identical with the one used in the momentum-energy method.

The boundary conditions have to be established. At the wall no slipping occurs, consequently:

$$\text{at } y = 0 \quad u = v = 0 \quad (3.54)$$

At the vapor interface the conditions are not simple as it was pointed out before. In order to obtain a similarity transformation, it may be assumed as an approximation that

$$\text{at } y = y_s, \quad \frac{\partial u}{\partial y} = 0 \quad (3.55)$$

This assumption leads to higher heat transfer rates than those predicted by the energy-momentum method.

The order of magnitude considerations applied in the derivation of the ordinary boundary layer equations can also be used in this case. As a result, the Navier-Stokes equations reduce to the following form,

$$\frac{\partial u}{\partial \xi} + u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = \frac{g(\rho_l - \rho_v) \sin \phi}{\rho_l} + \nu \frac{\partial^2 u}{\partial y^2} \quad (3.56)$$

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0 \quad (3.53)$$

These equations describe the flow without any heat transfer effects. To include these, the energy equation is needed in addition. The derivation of all these equations may be found in the references (43). For steady state conditions, the complete set of equations describing the flow and the heat transfer become,

$$u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = \frac{g(\rho_l - \rho_v) \sin \phi}{\rho_l} + \nu \frac{\partial^2 u}{\partial y^2} \quad (3.57)$$

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0 \quad (3.53)$$

$$\rho_e c_p \left( u \frac{\partial t}{\partial x} + v \frac{\partial t}{\partial y} \right) = k_e \frac{\partial^2 t}{\partial y^2} \quad (3.58)$$

The boundary conditions are:

$$\text{at } y = 0 \quad u = v = 0 \text{ and } t = t_w \quad (3.59)$$

$$\text{at } y = y_s \quad \frac{\partial u}{\partial y} = 0 \quad \text{and } t = t_s \quad (3.60)$$

These are actually the standard boundary layer equations with the additional assumptions that the buoyancy forces within the liquid and the viscous dissipation energy are negligible.

The problem now arises, how to solve these equations in particular cases. One obvious way is the numerical method applied directly to the above partial differential equations. An alternative approach is to reduce the partial differential equations to ordinary differential equations by the use of properly selected stream functions. This latter method is described in the following text. Denoting differentiation by a letter subscript, the stream function,  $\Psi$ , is defined in the usual manner that will automatically satisfy the continuity equation.

$$u = \Psi_y \quad (3.61)$$

$$v = -\Psi_x \quad (3.62)$$

The remaining two equations become:

$$\Psi_y \Psi_{xy} - \Psi_x \Psi_{yy} = \frac{g(\rho_e - \rho_o) \sin \phi}{\rho_e} + \nu \Psi_{yyy} \quad (3.63)$$

$$\Psi_y t_x - \Psi_x t_y = \alpha_e t_{yy} \quad (3.64)$$

where  $\alpha_t = \frac{k_e}{c_p \rho_e}$

The corresponding boundary conditions are:

$$\text{at } y = 0 \quad \Psi_y = 0, \quad \Psi_x = 0, \quad t = t_w \quad (3.65)$$

$$\text{at } y = y_s \quad \Psi_{yy} = 0, \quad t = t_s \quad (3.66)$$

Let

$$G(x) \equiv \frac{g(\rho_e - \rho_w) \sin \phi}{\rho_e} \quad (3.67)$$

Then the question is, for what types of functions of  $G(x)$  will the above relations reduce to ordinary differential equations. If this reduction can be accomplished, there is a transformation of the form:

$$\Psi = \alpha J(\eta) \cdot j(x) \cdot \bar{g}(y) \quad , \quad \text{where} \quad \eta = \eta(x, y) \quad (3.68)$$

which will indeed yield this result. Substituting relations (3.67) and (3.68) into (3.63) gives,

$$\begin{aligned} & \alpha^2 \left\{ J^2 [j j' (\bar{g}')^2 - j j' \bar{g} \bar{g}''] + J J' [j^2 \bar{g} \bar{g}' \eta_{xy} + j^2 (\bar{g}')^2 \eta_x - \right. \\ & \quad \left. - j^2 \bar{g} \bar{g}'' \eta_x - j j' \bar{g}^2 \eta_{yy}] + J J'' [j^2 \bar{g} \bar{g}' \eta_x \eta_y - j j' \bar{g}^2 \eta_y^2] + \right. \\ & \quad \left. + (J')^2 [j j' \bar{g}^2 \eta_y^2 + j^2 \bar{g}^2 \eta_y \eta_{xy} - j^2 \bar{g} \bar{g}' \eta_x \eta_y - j^2 \bar{g}^2 \eta_{xy}^2] \right\} = \\ & = G + \nu \alpha [J j \bar{g}''' + J' (3 j \bar{g}'' \eta_y + 3 j \bar{g}' \eta_{yy} + j \bar{g} \eta_{yyy}) + \\ & \quad + 3 J'' (j \bar{g}' \eta_y^2 + j \bar{g} \eta_y \eta_{yy}) + J''' (j \bar{g} \eta_y^3)] \quad (3.69) \end{aligned}$$

Obviously all coefficients of the function  $J$  and its derivatives must be of the form:  $G \cdot (\text{constant})$ , in order to render the expression reducible to an ordinary differential equation. If these coefficients are examined and it is noted that  $G$  must be a function of  $x$  only, then the following relations are found to exist,

$$\bar{g}(y) = E, \text{ a constant} \quad (3.70)$$

$$\eta_y = N(x) \quad (3.71)$$

Substituting into (3.69) produces,

$$\begin{aligned} \alpha^2 \left[ -JJ''(jj'E^2N^2) + (J')^2(jj'E^2N^2 + j^2E^2NN') \right] = \\ = G + \nu \alpha J'''(jEN^3) \end{aligned} \quad (3.72)$$

Divide both sides by  $\alpha^2(jj'E^2N^2)$ .

$$-JJ'' - (J')^2 \left( 1 + \frac{jN'}{Nj'} \right) = \frac{G}{\alpha^2 jj'E^2N^2} + \frac{\nu}{\alpha} J''' \left( \frac{N}{j'E} \right) \quad (3.73)$$

The coefficients of  $J'^2$  and  $J'''$ , in parentheses, are constant.

Therefore:

$$\frac{jN'}{Nj'} = B_0, \text{ a constant} \quad (3.74)$$

$$\frac{N}{j'E} = B_1, \text{ a constant} \quad (3.75)$$

Substituting  $N$  from (3.75) into (3.74) gives,

$$jj'' = B_0(j')^2 \quad (3.76)$$

All functions of  $j$  satisfying relation (3.76) will, therefore, reduce the equation to an ordinary differential equation, provided that the term containing  $G$  is also dimensionless. Dividing (3.76) by  $jj'$  results in an exact differential with the following solutions:

$$j = \begin{cases} |E_0 + E_1 x|^n & \text{when } B_0 \neq 1 \\ E_2 e^{E_3 x} & \text{when } B_0 = 1 \end{cases} \quad (3.77)$$

with the relation between  $B_0$  and  $n$ :

$$n = \frac{1}{1 - B_0} \quad (3.78)$$

Substituting these results into (3.73) shows the types of functions for  $G$  that will allow a transformation of this kind to be performed.

When  $B_0 \neq 1$ :

$$G = E_4 |E_0 + E_1 x|^{4n-3} \quad (3.79)$$

When  $B_0 = 1$

$$G = E_5 e^{4E_3 x} \quad (3.80)$$

It is convenient to express all functions in terms of the variation of gravity along the plate,  $G$ .

For the first class of allowable functions,

$$G = E_4 |E_0 + E_1 x|^m \quad (3.79)$$

$$j \sim |E_0 + E_1 x|^{\frac{m+3}{4}} \quad (3.79a)$$

$$N \sim |E_0 + E_1 x|^{\frac{m-1}{4}} \quad (3.79b)$$

$$\eta \sim |E_0 + E_1 x|^{\frac{m-1}{4}} \cdot y \quad (3.79c)$$

$$\Psi \sim J |E_0 + E_1 x|^{\frac{m+3}{4}} \quad (3.79d)$$

For the second class,

$$G = E_5 e^{\frac{E_6 x}{4}} \quad (3.80)$$

$$j \sim e^{\frac{E_6 x}{4}} \quad (3.80a)$$

$$N \sim e^{\frac{E_6 x}{4}} \quad (3.80b)$$

$$\eta \sim e^{\frac{E_6 x}{4}} \cdot y \quad (3.80c)$$

$$\Psi \sim J e^{\frac{E_6 x}{4}} \quad (3.80d)$$

Equation (3.73), defining  $J$ , now can be written in the following form:

$$J''' + \frac{\alpha}{\nu B_1} J J'' - \frac{\alpha}{\nu B_1} \left( 1 + \frac{j j''}{(j')^2} \right) (J')^2 + \frac{G}{\nu \alpha B_1^3 E^4 j (j')^3} = 0 \quad (3.81)$$

This is a variation of the well-known Falkner-Skan equation appearing in boundary layer theory.

The energy equation can now be investigated separately. From (3.68), (3.71), and (3.75), the following relation can be found,

$$\eta = B_1 E j' y \quad \text{such that } \eta = 0 \text{ when } y = 0 \quad (3.82)$$

$$\Psi = \alpha E J j \quad (3.83)$$

Substituting into equation (3.64) yields:

$$\alpha B_1 E^2 J' j j' t_x - (\alpha B_1 E^2 J' j j'' y + \alpha E J j') t_y = \alpha_t t_{yy} \quad (3.84)$$

In order to render this equation dimensionless, define,

$$T(\eta) = \frac{t_s - t}{t_s - t_w} = \frac{t_s - t}{\Delta t} \quad (3.85)$$

where  $\Delta t$  may be a function of  $x$  only. Then, if  $t_s$  remains constant, equation (3.84) becomes

$$\begin{aligned} & (\alpha B_1 E^2 J' j j') (-B_1 E j'' y T' \Delta t - T \Delta t_x) - (\alpha B_1 E^2 J' j j'' y + \\ & + \alpha E J j') (-B_1 E j' T' \Delta t) = -\alpha_t B_1^2 E^2 (j')^2 T'' \Delta t \end{aligned} \quad (3.86)$$

Performing the operations and making the equation dimensionless yields,

$$T'' + \frac{\alpha}{\alpha_t B_1} \left[ J T' - \left( \frac{j \Delta t'}{j' \Delta t} \right) J' T \right] = 0 \quad (3.87)$$

Accordingly, if  $\frac{j}{j'} \cdot \frac{\Delta t'}{\Delta t}$  is a constant, the energy equation will also be reduced to an ordinary differential equation by the previous transformations.

Thus equations (3.63) and (3.64) may be transformed into the following ordinary differential equations,

$$J''' + \frac{\alpha}{\nu B_1} \left[ J J'' - (1 + E_7)(J')^2 \right] + \frac{E_8}{\nu \alpha B_1^3 E_4} = 0 \quad (3.88)$$

$$T'' + \frac{\alpha}{\alpha_t B_1} \left[ J T' - E_9 J' T \right] = 0 \quad (3.89)$$

where  $E_7 \equiv \frac{j j''}{(j')^2}$ ,  $E_8 \equiv \frac{G}{j(j')^3}$ , and  $E_9 \equiv \frac{j}{j'} \cdot \frac{\Delta t'}{\Delta t}$  (3.90a, b, c)

The boundary conditions are:

at  $\eta = 0$   $J = 0, J' = 0, T = 1$  (3.91)

at  $\eta = \eta_s$   $J'' = 0, T = 0$  (3.92)

These equations can be solved for any known value of  $\eta_s$ . In order to find  $\eta_s$  along the surface, an energy balance equation may be written between two cross sections of the condensate layer,  $x = x_0$  and  $x = x_s$ .

$$\int_{x_0}^{x_s} k_e \left( \frac{\partial t}{\partial y} \right)_{y=0} dx = \int_0^{y_s} \lambda \rho_e u dy + \int_0^{y_s} \rho_e u c_{pe} (t_s - t) dy \quad (3.93)$$

This equation is the same as (3.2) the energy equation of the momentum-energy method. Substituting the previous dimensionless relations leads to the following derivation,

$$\begin{aligned} -k_e T'(0) B_1 \int_{x_0}^{x_s} \Delta t j' dx &= \lambda \rho_e \alpha_j \int_0^{\eta_s} J'(1 + ST) d\eta \\ -\frac{B_1 k_e T'(0)}{1 + E_9} \left[ \Delta t j - \Delta t(x_0) j(x_0) \right] &= \\ &= \lambda \rho_e \alpha_j \left[ J(\eta_s) - J(0) + S \int_0^{\eta_s} J' T d\eta \right] \end{aligned} \quad (3.94)$$

The integral can be eliminated by using equation (3.89) together with its boundary conditions (3.91) and (3.92).

$$-\frac{B_1 k_e T'(0)}{1+E_q} \left[ \Delta t_j - \Delta t(x_0) j(x_0) \right] =$$

$$= \lambda \rho_e a_j \left\{ J(\eta_s) + \right.$$

$$\left. + \frac{\beta}{1+E_q} \int_0^{\eta_s} \left[ (JT)' + \frac{\alpha_2 B_1}{a} T'' \right] d\eta \right\}$$

$$\frac{B_1 k_e T'(0) \Delta t(x_0) j(x_0)}{1+E_q} =$$

$$= \lambda \rho_e a_j J(\eta_s) + \frac{B_1 k_e \Delta t_j T'(\eta_s)}{1+E_q} \quad (3.95)$$

This equation then determines  $\eta_s$ . If  $\Delta t(x_0)$  or  $f(x_0)$  is equal to zero, however, further simplification is possible which results in the following expression:

$$\frac{J(\eta_s)}{T'(\eta_s)} = \frac{B_1 k_e \Delta t}{(1+E_q) \lambda \rho_e a} \quad (3.96)$$

It is clear now that, if  $\Delta t$  is constant,  $\eta_s$  is independent of  $x$ . In the above equation "a" may be set equal to  $\alpha_t$ , and  $E$  may be selected such that the constant in equation 3.88 is unity.  $B_1$  is essentially arbitrary. The equations then become,

$$J''' + \frac{1}{B_1 \overline{Pr}} \left[ J J'' - (1 + E_7) (J')^2 \right] + 1 = 0 \quad (3.88a)$$

$$T'' + \frac{1}{B_1} \left[ J T' - E_9 J' T \right] = 0 \quad (3.89a)$$

$$\frac{J(\eta_s)}{T'(\eta_s)} = - \frac{B_1}{1 + E_9} \cdot \frac{c_p \rho \Delta t}{\lambda} = - \frac{B_1}{1 + E_9} \zeta \quad (3.96a)$$

Examining the set of permissible functions reveals that the flat plate problem with constant  $G$  can indeed be solved by this method, but the circular tube with  $G$  varying as  $\sin x$  cannot be solved directly. Sparrow presented the flat plate solution, and later used Hermann's (21) approximate function to obtain a solution to the circular tube problem (46, 47).

In finding an approximate solution, Hermann matched the constants of a set of four equations such that these equations were satisfied exactly at  $\phi = \pi/2$ . Since no similarity exists at this point, while at  $\phi = 0$  it does, this approximation is certainly no better than Chen's described before.

Comparing the energy-momentum method to Sparrow's results, as shown in Figure 3.3, indicates that the previous one yields consistently lower values for the heat transfer rate. The discrepancy is due obviously to the difference in the interface boundary conditions.

The ones assumed in the momentum-energy method conform closer to the usual physical situation existing, such as an essentially stagnant vapor condensing on a surface.

Since for ordinary fluids the corrections are insignificant, the results of all these methods will have to be compared to those obtained from data on liquid metals. It was mentioned before that Misra and Bonilla's results qualitatively show the marked reduction in heat transfer rates for liquid metals.

## CHAPTER IV

## THE AXIALLY FLOWING CONDENSATE ON THE BOTTOM OF THE TUBE

It is evident that all the condensate formed inside the tube has to leave through the outlet end. If there is a considerable amount of vapor passing through the tube, such as in the first pass of a multi-pass condenser, then the shear exerted on the surface of the liquid by the relatively fast-moving vapor controls the flow pattern and the effect of gravity becomes negligible. Experimental proof may be found in the fact that the data obtained in horizontal and in vertical tubes can be correlated by the same curve above a certain Reynolds number (2).

If, however, the tube is part of a single-pass condenser, then the vapor shear is zero at the outlet and negligible for a certain distance upstream. Now gravity is the controlling factor at least in the downstream portion of the tube. This is the problem to be investigated in the following section.

Free-Surface Flow . . . An Old Problem with a New Twist

If vapor shear is relatively low, the condensate forming on the sides of the tube collects on the bottom; then it has to flow out axially and is discharged at the outlet. The depth of this axial flow has a marked influence on the heat transfer. This depth is considerably larger than the thickness of the condensate film on the sides. Therefore, the axial condensate flow reduces the effective heat transfer area in the tube. It will be shown later, quantitatively, that the amount of heat passing through the bottom condensate layer is negligible compared to the heat transferred on the side walls.

Consequently, as far as the overall problem is concerned, the most important factor is the depth of the flow. If the depth could be established, the effective heat transfer area could also be found.

The problem of liquid discharge from a partially filled tube, or the more general problem of liquid discharge from any open channel has been an old one, in particular, with the civil engineers. They have been confronted with such problems ever since they undertook the task of controlling rivers, harbors, and building hydraulic structures such as channels or dams. On examining their work in this field, one can find a problem which is very closely related to the one at hand. This is the discharge from a so-called lateral spillway. Here the liquid is fed into the open channel all along its length and is discharged through one end. The similarity to the condensate flow problem is obvious. Upon closer examination, however, some rather important differences occur. First of these is the size. Compared to even the largest condenser tube used in practice, the smallest lateral spillway or any similar structure is enormous. As a result, the lateral spillway contains usually turbulent flow, while the condensate flow can be laminar, transient, or turbulent, with the laminar type usually dominating a great part of the tube. In the case of turbulent flow the velocity distribution is much more uniform than in the laminar or even transient case. Thus, the lateral spillway problem is much more amenable to a one-dimensional analysis, although the methods used can be applied in either case. Another important difference arises from the axial vapor shear acting on the surface of the condensate layer in the upstream portion of the tube. This affects

the flow pattern in several ways, two of which are the tendency to reduce the depth and to induce rather strong traveling waves on the surface. The first of these increases, the second decreases the effective heat transfer area. A third difference between the two types of phenomena is that the amount of condensate feeding into the bottom layer at any point along the tube depends on the depth, while in a lateral spillway such an interdependence usually does not exist.

What are exactly the characteristics of the phenomena occurring on the bottom of the tube? In order to answer this question as thoroughly as possible it is not enough to investigate the axial flow all by itself. The interactions at the boundaries, such as vapor shear at the free surface, and their possible effects on the flow should also be considered, at least qualitatively.

The axial flow of condensate is non-uniform in two respects. First the quantity flowing increases downstream; second the cross-section changes along the length. Of primary interest here is the latter variation: the establishment of the surface profile. There are actually two parts to this problem: one is to find a control point or cross-section at which the depth may be predicted; the other is to determine the change of depth, starting from the control section, all along the tube. On both of these problems there was a great amount of work done, in particular, by the civil engineers who needed methods for predicting open channel flows (23)(32).

### The Critical Depth of Free-Surface Flows

The problem of establishing a control point has been approached through the use of the so-called critical depth theory. This states that in a free surface flow at some point the specific energy of the stream will go through a minimum. The specific energy of the stream may be defined as follows:

$$H = \frac{1}{\rho_m V_m A} \int_A \left( \frac{p}{\rho g} + \frac{V^2}{2g} + s \right) \rho V dA \quad (4.1)$$

where  $H$  specific head, ft

$\rho$  density, slugs/ft<sup>3</sup>

$V$  velocity, ft/sec

$A$  cross-sectional area of flow, perpendicular to the stream lines, ft<sup>2</sup>

$p$  pressure, lbf/ft<sup>2</sup>

$g$  gravitational acceleration, ft/sec<sup>2</sup>

$s$  elevation above a given datum level, ft

subscript  $m$  - mean value

To illustrate this theory and its implications, first the flow in a rectangular channel will be investigated with the assumptions that the velocity and density distributions are uniform and that the pressure distribution is hydrostatic, that is, the streamlines are essentially straight. Defining the depth of the liquid by  $h$ , the above equation becomes,

$$H = \frac{v^2}{2g} + h + s_0 \quad (4.2)$$

where  $s_0$  elevation of the channel bottom above a datum, ft

$h$  depth of flow, ft

For a given flow rate,  $Q$  ft<sup>3</sup>/sec, and flow rate per unit width of the channel,  $q = \frac{Q}{b}$  ft<sup>3</sup>/sec-ft, the velocity may be expressed as

$$V = \frac{Q}{bh} = \frac{q}{h} \quad (4.3)$$

Substituting into (4.2) yields:

$$H = \frac{q^2}{2gh^2} + h + s_0 \quad (4.4)$$

For the given cross-section taking  $s_0 = 0$ , specific head versus depth plots in a family of curves with the flow rate as an independent parameter. A typical graph is shown in Figure 4.1.

The minimums of the specific head curves may be found by differentiating equation (4.4) with respect to  $h$  and setting the result equal to zero.

$$\frac{\partial H}{\partial h} = -\frac{q^2}{gh_c^3} = 0$$

$$h_c = \sqrt[3]{\frac{q^2}{g}} \quad (4.5)$$

Some physical significance may be found in this expression if the corresponding critical velocity is calculated.

$$V_c = \sqrt{gh_c} \quad (4.6)$$

This expression is identical with the velocity of wave propagation on the surface of a liquid  $h_c$  deep. Thus the critical depth and the corresponding critical flow is analogous to the sonic flow occurring at the throat of a nozzle or at the outlet of a duct.

Equation (4.4) and the corresponding curves in Figure 4.1 show that for any specific heat greater than the minimum two alternate depths may exist, one greater and one smaller than the critical depth. Correspondingly the velocities are either sub- or supercritical. Which one of these flows exists in a given channel depends on how the fluid enters at the upstream end, the losses occurring in the channel, and the slope of the channel. In a long horizontal tube, the flow will always become subcritical provided no shear stress exists at the free surface to impart energy to the fluid. If at the outlet end there is a change to a steeper slope or a so-called free discharge exists, the control point in the form of critical depth must occur near this end. The exact location depends on how the transition from subcritical to supercritical flow occurs. This transition in turn is influenced primarily by the geometry of the channel near the outlet. It has been established experimentally in hydraulics that the critical depth actually occurs a very short distance (about 3 or 4 times the depth) upstream of a so-called free overfall. If the transition geometry is gradual, such as in the case of an elbow at the outlet, the critical depth would occur somewhere in the elbow. This is one of the possible reasons for lower surface profiles found (15) in horizontal pipes with elbows at the outlet. At very low flow rates surface tension effects become more important and tend to raise the top of the liquid layer. In the case of the free overfall, at low flow rates the liquid will

not separate from the tube but will adhere to the lip and flow downward. By increasing the pressures in the flow at the outlet, this effect also tends to raise the surface level.

The effect of non-uniform velocity distribution on the critical depth should be investigated next. If the bottom of the channel is taken as datum, equation (4.1) may be written (23) as:

$$H = \alpha \frac{Q^2}{2gA^2} + \beta h \quad (4.7)$$

where

$$\alpha = \frac{1}{AV_m^3} \int_A V^3 dA \quad (4.8)$$

$$\beta = \frac{1}{Qh} \int_A \left( \frac{p}{\rho g} + s \right) V dA \quad (4.9)$$

Thus  $\alpha$  is a function of the velocity distribution; while  $\beta$  is a function of the velocity distribution, and it also depends on the curvature of the streamlines, that is, the deviation of the pressure from hydrostatic. In particular, if the pressure is exactly hydrostatic,  $\beta = 1$ . If the streamlines curve downward  $\beta < 1$ , if they curve upward  $\beta > 1$ . For fully developed, laminar flow in a pipe  $\alpha = 2$ .

Now the minimum energy principle may be stated as:

$$\frac{\partial H}{\partial h} = \frac{Q^2}{2gA^2} \cdot \frac{\partial \alpha}{\partial h} + \alpha \frac{\partial}{\partial h} \left( \frac{Q^2}{2gA^2} \right) + \beta + h \frac{\partial \beta}{\partial h} = 0 \quad (4.10)$$

If it is assumed that the variation of  $\alpha$  and  $\beta$  are small near the critical depth, the above equation simplifies to:

$$\frac{\alpha}{\beta} \frac{\partial}{\partial h} \left( \frac{Q^2}{2gA^2} \right) + 1 = 0 \quad (4.11)$$

Again investigate the two-dimensional flow.

$$\frac{\alpha}{\beta} \frac{\partial}{\partial h} \left( \frac{Q^2}{2gh^2} \right) + 1 = 0$$

$$-\frac{\alpha}{\beta} \cdot \frac{Q^2}{gh^3} + 1 = 0$$

$$h_c = \sqrt[3]{\frac{\alpha}{\beta} \cdot \frac{Q^2}{g}} \quad (4.12)$$

Thus non-uniform velocity distributions tend to increase the depth.

From the foregoing discussion the following general conclusions may be drawn:

- a. In order to be able to use the critical depth theory successfully, a horizontal channel or tube with a sharp cut-off should be used. Then the critical depth will always occur in the horizontal part near the outlet end. If the length-diameter ratio of the tube is large, the exact location of this control point becomes unimportant.
- b. The critical depth theory is expected to predict depths that are too low when the flows are small, particularly if the velocity distribution is neglected in the calculations.

Now consider the circular cross-section of figure 3.2.

$$A = r_0^2 (\theta_c - \sin \theta_c \cos \theta_c) \quad (4.13)$$

$$h = r_0 (1 - \cos \theta_c) \quad (4.14)$$

$$\frac{\partial}{\partial h} = r_0 \sin \theta_c \frac{\partial}{\partial \theta_c} \quad (4.15)$$

Substituting into equation (4.11), and simplifying yields,

$$\frac{16\alpha}{\beta} \cdot \frac{Q^2}{gr_0^5} = \frac{(2\theta_c - \sin 2\theta_c)^3}{\sin \theta_c} = \frac{(\phi_c - \sin \phi_c)^3}{\sin \frac{\phi_c}{2}} \quad (4.16)$$

This function is plotted together with some of the experimental results in Figure 7.1. If  $\alpha/\beta$  is assumed to be equal to unity, the correlation with experimental data is rather good at high flow rates, above  $Q/\sqrt{gr_0^5} = 0.15$ , and becomes progressively worse at lower flow rates. If, for laminar flows,  $Re < 3,000$ , it is assumed that  $\alpha/\beta = 2$ , the correlation becomes more satisfactory; although the deviation still remains considerable at the lowest flow rates.

Equation (4.16) can be expressed in another form which allows a very accurate approximation in terms of the depth-diameter ratio,  $h/D$ . Define the section factor as:

$$Z = A\sqrt{\frac{A}{b}} \quad (4.17)$$

where  $Z$  section factor, ft<sup>2.5</sup>

$A$  cross-sectional area of flow, ft<sup>2</sup>

$b$  top width of flow, ft

For the circular cross-section at the critical point

$$Z_c = \frac{r_o^{2.5} (\phi_c - \sin \phi_c)^{\frac{3}{2}}}{4 \left( \sin \frac{\phi_c}{2} \right)^{\frac{1}{2}}} = Q \sqrt{\frac{\alpha}{\beta g}}$$

$$\frac{Z_c}{r_o^{2.5}} = \sqrt{\frac{\alpha}{\beta}} \cdot \frac{Q}{\sqrt{g r_o^5}} = \frac{(\phi_c - \sin \phi_c)^{\frac{3}{2}}}{4 \left( \sin \frac{\phi_c}{2} \right)^{\frac{1}{2}}} \quad (4.18)$$

If  $Z/r_o^{2.5}$  is expressed in terms of  $h_c/d_o$ , the resulting relation can be approximated for the range  $0.02 < h_c/d_o < 0.9$  by the following relation:

$$\frac{Z_c}{r_o^{2.5}} = 5.426 \left( \frac{h_c}{d_o} \right)^{1.956} \quad (4.19)$$

This expression is practically exact for the range  $0.04 < h_c/d_o < 0.85$ , and it is 12% too high at  $h_c/d_o = 0.02$ , 7% too low at  $h_c/d_o = 0.9$ . Since  $Z$  goes to infinity as  $h_c/d_o$  approaches one, the approximate relation should not be used beyond the limits specified.

Substituting (4.19) into (4.18) yields:

$$\sqrt{\frac{\alpha}{\beta}} \cdot \frac{Q}{\sqrt{g r_o^5}} = 5.426 \left( \frac{h_c}{d_o} \right)^{1.956} \quad (4.20a)$$

or

$$\frac{h_c}{d_o} = 0.4212 \left( \sqrt{\frac{\alpha}{\beta}} \cdot \frac{Q}{\sqrt{g r_o^5}} \right)^{0.5112} \quad (4.20b)$$

These equations then relate theoretically the flow rate and the critical depth for a circular tube. For the range investigated in the experiments,  $\sqrt{\alpha/\beta}$  may be assumed to be 1.4 for  $Re < 3000$  (based on the hydraulic diameter of the flow) and 1.1 for  $Re > 3000$ .

The experimental work showed excellent agreement with these relations for high flow rates. For low flow rates of  $Q_1/\sqrt{gr_o^5} < 0.08$ , however, the correlation became progressively worse, primarily because surface tension prevented the formation of a free nappe, and the liquid adhered to the lip of the tube. The experimental results indicate that for these lower flow rates the central angle subtended by the condensate near the outlet remains constant at  $\phi_1 = 90^\circ$  (see Figure 7.1).

#### The Profile of the Free Surface

In hydraulics the problem of predicting free-surface profiles, the so-called backwater curves, has been studied for a long time. As a result, there is an extensive literature available as reference; and all text books in hydraulics treat this problem more or less in detail (23)(43). Their analyses, however, do not consider any shear acting on the surface of the flow; and they are usually one-dimensional. Also, most of the investigators are dealing with uniform flow rates along the channels, with relatively few examining the effect of such a variation. Li (33) derived equations for surface profiles in rectangular and triangular horizontal channels, with the assumptions that the velocity distribution is uniform, friction may be neglected, and the flow rate varies linearly along the length. His estimates of the friction effect indicated that the calculated upstream depth would have increased by not more than 10% in the most extreme cases.

Let us examine the problem of condensate flow inside a circular tube by developing the generalized one-dimensional continuous flow equations for a two-phase mixture with condensation.

Equations of State:

For the liquid density

$$\rho_l = \text{constant} \quad (4.21a)$$

For the vapor of an ordinary refrigerant under the usual operating conditions the pressure drop along a condenser tube is small compared to the absolute pressure. Consequently, the density,

$$\rho_v = \text{constant} \quad (4.21b)$$

Velocity of Surface Waves on the Bottom Condensate Layer:

$$c^2 = \frac{gA_l}{b} \quad (4.22a)$$

where  $c$  Velocity of surface wave, ft/sec

$g$  Gravitational acceleration, ft/sec<sup>2</sup>

$A_l$  Liquid cross-sectional area, ft<sup>2</sup>

$b$  Width of the liquid free surface, ft

In differential form

$$\frac{dc}{c} = \frac{1}{2} \left( \frac{dA_l}{A_l} - \frac{db}{b} \right) \quad (4.22b)$$

Definition of the Froude Number:

$$\overline{Fr}^2 = \frac{Q_l^2}{A_l^2 c^2} = \frac{Q_l^2 b}{g A_l^3} \quad (4.23a)$$

$$\frac{d\overline{Fr}^2}{\overline{Fr}^2} = \frac{dQ_l^2}{Q_l^2} + \frac{db}{b} - \frac{dA_l^3}{A_l^3} \quad (4.23b)$$

where  $\overline{Fr}$  Froude Number

$Q_l$  Liquid volumetric flow rate, ft<sup>3</sup>/sec

With the above definition a Froude Number of unity corresponds to the critical depth in any cross-section.

Continuity:

$$\Gamma_l = Q_l \rho_l \quad (4.24a)$$

$$\Gamma_v = Q_v \rho_v \quad (4.24b)$$

$$\Gamma_l + \Gamma_v = \Gamma_{in} \quad (4.25a)$$

$$d\Gamma_l = -d\Gamma_v \quad (4.25b)$$

$$dQ_v = -\frac{\rho_l}{\rho_v} dQ_l \quad (4.26)$$

where  $\Gamma_v$  and  $\Gamma_l$  Vapor and liquid mass flow rates, slugs/sec

$Q_v$  Vapor volumetric flow rate, ft<sup>3</sup>/sec

Energy Equation for Overall Heat Transfer:

$$h_m A_h \Delta t_m = \Gamma_{in} (h_{in} - h_{out}) \quad (4.27)$$

where  $h_m$  Heat transfer coefficient, Btu/sec ft<sup>2</sup> °F

$A_h$  Heat transfer area, ft<sup>2</sup>

$\Delta t_m$  Mean temperature differential between vapor and surface, to be considered as a constant, °F

$\Gamma_{in}$  Total mass flow rate at any cross section, slugs/sec

$h_{in}$  and  $h_{out}$  Enthalpies at inlet and exit, Btu/slug

## Energy Equation for Liquid Flow:

Equation 4.2 has to be modified to include the effect of a variable pressure in the vapor phase. Thus,

$$H = \frac{p}{\rho_l g} + h + s_o + \frac{Q_l^2}{2gA_l^2} \quad (4.28a)$$

$$dH = \frac{dp}{\rho_l g} + dh + ds_o + \frac{Q_l^2}{2gA_l^2} \left( \frac{dQ_l^2}{Q_l^2} - \frac{dA_l^2}{A_l^2} \right) \quad (4.28b)$$

## Momentum Equations:

For the vapor phase,

$$-A_v dp - \tau_s P_v dz = C_v d \left( \frac{\rho_v Q_v^2}{A_v} \right) \quad (4.29)$$

where  $A_v$  Vapor cross-sectional area, ft<sup>2</sup>

$P_v$  Wetted perimeter of vapor, ft

$z$  Axial direction, ft

$\tau_s$  Vapor wall shear stress, lbf/ft<sup>2</sup>

$C_v$  Correction factor for velocity distribution

For the liquid phase

$$\begin{aligned} & -A_l dp - d(\rho_l g A_l s_c) + \tau_s b dz - \\ & -\tau_w P_w dz + \rho_l g A_l \frac{ds_o}{dz} dz = \\ & = C_v d \left( \frac{\rho_l Q_l^2}{A_l} \right) - 2 \int_0^{z+dz} \int_0^{y_s} \rho_l u w dy dz \end{aligned} \quad (4.30)$$

wall condensate

where  $s_c$  Depth of centroid of  $A_f$  below free surface, ft

$\tau_w$  Liquid shear stress on walls, lbf/ft<sup>2</sup>

$P_w$  Wetted perimeter of liquid on walls, ft

$u, w$  Velocity components of condensate layer on walls where it reaches the bottom condensate

The shear stresses may be expressed as follows

$$\tau_s = f_v \rho_v \frac{Q_v^2}{2A_v^3} \quad (4.31a)$$

$$\tau_w = f_l \rho_l \frac{Q_l^2}{2A_l^3} \quad (4.31b)$$

where  $f_v$  and  $f_l$  are friction factors for the vapor and the liquid, and can be approximated by the usual expressions in terms of the Reynolds number.

$$f_v = a_i (\overline{Re}_v)^{b_i} = a_i \left( \frac{4\rho_v Q_v}{\mu_v P_w} \right)^{b_i} \quad (4.32a)$$

$$f_l = a_i (\overline{Re}_l)^{b_i} = a_i \left( \frac{4\rho_l Q_l}{\mu_l P_w} \right)^{b_i} \quad (4.32b)$$

Based on Gazley's data (16), the constants may be taken as follows

$$\text{for } Re < 3000 \quad a_i = 18, b_i = -1, C_v = 1.33 \quad (4.33a)$$

$$\text{for } Re > 3000 \quad a_i = 0.0085, b_i = 0, C_v = 1 \quad (4.33b)$$

Geometry of Flow:

All geometrical functions may be expressed in terms of  $\theta_c$ , half of the central angle subtended by the bottom condensate layer.

$$\phi_c = 2\theta_c \quad (4.34a)$$

$$\phi = \pi - \theta_c \quad (4.34b)$$

$$b = 2r_0 \sin \theta_c \quad (4.34c)$$

$$A_e = r_0^2 \left( \theta_c - \frac{\sin 2\theta_c}{2} \right) \quad (4.34d)$$

$$A_o = r_0^2 \left( \pi - \theta_c + \frac{\sin 2\theta_c}{2} \right) \quad (4.34e)$$

$$h = r_0 (1 - \cos \theta_c) \quad (4.34f)$$

$$P_o = 2r_0 (\pi - \theta_c + \sin \theta_c) \quad (4.34g)$$

$$P_w = 2r_0 \theta_c \quad (4.34h)$$

$$A_e s_c = r_0^3 \left[ \frac{2}{3} \sin^3 \theta_c - \cos \theta_c \left( \theta_c - \frac{\sin 2\theta_c}{2} \right) \right] \quad (4.34i)$$

Some of these functions are tabulated in Appendix VI.

#### Additional Relations:

Based on equations (3.9) and (3.17), using the constants  $A_o$ ,  $B_o$ , and  $D_o$  of the first approximation (see page 23) and Rohsenow's (40) value of 0.68 for  $C$ , and noting that the change of volumetric flow rate  $dQ_e/dz = 2f$ , the following relation may be established.

$$dQ_e = 2 \left[ \frac{g(\rho_l - \rho_v) k_e^3 r_0^3 \Delta t^3}{3\mu_e \rho_e^3 \lambda^3 (1+0.68S)^3} \right]^{1/4} \left[ \frac{4}{3} \int_0^\phi \sin^{1/3} \phi d\phi \right]^{3/4} dz = \Omega dz \quad (4.36)$$

The last term of equation (4.30) may be estimated by integrating the velocity profiles of equations (5.2) and (5.5) together with relations (3.6), (3.9), and (3.17).

$$\underbrace{2 \int_0^{z+dz} \int_0^{r_s} \rho_e u w dy dz}_{\text{wall condensate}} = \left[ \frac{5 k_e r_0 T_s \Delta t}{3\mu_e \lambda (1+0.68S)} \right] \left[ \frac{\int_0^\phi \sin^{1/3} \phi d\phi}{\sin^{1/3} \phi} \right] dz \quad (4.37)$$

The last expression, the momentum influx of the wall condensate, is based on the assumption that the condensate on the bottom and on the walls meet at an angle. Physically this situation is impossible; surface tension will create a smooth transition which will considerably increase the thickness of the wall condensate and, consequently, reduce the magnitude of the term. Since this effect is small to begin with, it is reasonable to omit it entirely.

For the determination of the liquid surface profile equation (4.30) has to be solved. Dividing this expression by  $\rho_l g r_o^3$ , and defining  $\sigma \equiv ds/dz$  results:

$$d\left(\frac{A_e s_c}{r_o^3}\right) = \left[ \frac{A_e \sigma}{r_o^3} + \frac{\tau_s b}{\rho_l g r_o^3} - \frac{\tau_w P_w}{\rho_l g r_o^3} - \frac{A_e}{r_o^2} \frac{d}{dz} \left( \frac{p}{\rho_l g r_o} \right) - 2C_v \frac{d}{dz} \left( \frac{Q_e^2}{A_e g r_o^3} \right) \right] dz \quad (4.38)$$

The numerical solution of this equation may be simplified by the following assumptions. First the vapor friction factor,  $f_v$ , may be considered a constant, 0.0085, even in the laminar region. Since the vapor shear is very small for  $Re_v < 3000$ , this simplification will not introduce a serious error. Second, the liquid feed rate  $\Omega = dQ/dz$  may be taken as constant along the tube. Experimental evidence, as shown in the data in Appendix III, Table A-6, indicates that for the range of flow rates examined, the liquid level was very uniform for most part of the tube. For the inclined tube the liquid

depth was observed to be essentially constant after the initial liquid ramp reported in Appendix III, Table A-5. Examining the angle function in equation (4.36), tabulated in Appendix VI, reveals that  $\Omega$  is not too sensitive to variations of  $\phi$  in the range of  $120^\circ$  to  $160^\circ$ . Consequently, the error caused by this assumption can be easily minimized by selecting a good mean value for the condensate depth when determining  $\Omega$ . The resulting relations become,

$$-\frac{dp}{dz} = \frac{0.00425\rho_v Q_v^2 P_v}{A_v^3} + \frac{2\rho_v Q_v}{A_v^2} \cdot \frac{dQ_v}{dz} \quad (4.39)$$

where the factor  $C_v$  was taken as unity.

$$Q_v = \Omega z \quad (4.40)$$

$$Q_v = \Omega \frac{\rho_l}{\rho_v} (L - z) \quad (4.41)$$

Substituting into (4.38) yields:

$$\begin{aligned} d\left(\frac{A_e s_c}{r_o^3}\right) &= \\ &= \left\{ \frac{A_e \sigma}{r_o^3} + \frac{0.00425 \Omega^2 \rho_l (L-z)^2 b}{A_v^2 \rho_v g r_o^3} - \frac{9 \mu_l \Omega z P_v^2}{4 A_e^2 \rho_l g r_o^3} + \right. \\ &\left. + \frac{A_e \rho_l \Omega^2}{A_v^2 \rho_v g r_o^3} \left[ \frac{0.00425 P_v (L-z)^2}{A_v} - 2(L-z) \right] - \frac{d}{dz} \left[ \frac{1.33 \Omega^2 z^2}{A_l g r_o^3} \right] \right\} dz \quad (4.42) \end{aligned}$$

The liquid flow was assumed to be laminar everywhere. This was actually the case for all condensation experiments.

This equation may be integrated numerically, provided that the geometry is known at one point. For a horizontal tube or for a very slightly downward tilted tube, where the downstream liquid flow is definitely subcritical, a critical depth will exist at the outlet. As it was pointed out previously, at low flow rates the outlet end still controls the flow, but the depths are considerably increased due primarily to surface tension effects. The depth of flow becomes less as the inclination is increased; the exposed wall area, and consequently the effective heat transfer increases. This improvement, however, is eventually counteracted by the effect the inclination produces on the wall condensate. Hassan and Jakob (19) showed that, theoretically, the heat transfer rate varies as  $\cos^{1/4}(\sin^{-1} \sigma)$  during condensation on an infinite circular tube. As long as  $2 r_o \tan(\sin^{-1} \sigma) \ll L$ , this relation is the best available estimate of the influence of inclination on the heat transfer through the wall condensate. The experimental data Appendix III, Table A-5, show a considerable decrease in condensate depth as the tube is tilted a small amount of the order of  $\sigma = 0.010$ , but tilting the tube further did not affect the depth very much.

For inclined tubes the establishment of a control section becomes very difficult, if not well nigh impossible. One may argue that under such conditions the flow depth starts at zero at the inlet. This assumption leads to a numerical step-by-step solution of equation (4.42). On the other hand, careful consideration of the flow patterns observed in the experiments suggest another type of boundary condition, which not only gives very good results, but also renders the mathematical solution extremely simple.

Again the experimental observations revealed that the flow depths were very uniform along most of the tube. The only departure from near uniform depth occurred near the entrance region and, in the horizontal tube, very close to the outlet end. This observation suggests for a boundary condition that the depth should remain very nearly constant in the downstream portion of the tube. Such an assumption will lead to the elimination of the terms containing area variations after equation (4.42) is integrated, and the resulting relation becomes:

$$\begin{aligned} & \frac{L}{r_0} \cdot \frac{A_e}{r_0^2} \sigma \left[ z^+ \right]_1^2 - \\ & - 0.001417 \frac{\rho_e}{\rho_w} \cdot \frac{\Omega^2 L^2}{g r_0^5} \cdot \frac{L}{r_0} \left( \frac{r_0^2}{A_w} \right)^2 \sin \theta_c \left[ (1-z^+)^3 \right]_1^2 - \\ & - 1.125 \frac{\Omega^2 L^2}{g r_0^5} \cdot \frac{\mu_e}{\rho_e \Omega} \left( \frac{r_0}{r_{he}} \right)^2 \left[ z^{+2} \right]_1^2 + \\ & + \frac{\rho_e}{\rho_w} \cdot \frac{\Omega^2 L^2}{g r_0^5} \cdot \frac{A_e}{r_0^2} \left( \frac{r_0^2}{A_w} \right)^2 \left[ (1-z^+)^2 - 0.001417 \frac{L}{r_0} \cdot \frac{r_0}{r_{he}} (1-z^+)^3 \right]_1^2 - \\ & - 2.67 \frac{r_0^2}{A_e} \cdot \frac{\Omega^2 L^2}{g r_0^5} \left[ z^{+2} \right]_1^2 = 0 \end{aligned} \quad (4.43)$$

where  $z^+ = \frac{z}{L}$

$$r_h = \frac{A}{P}$$

$\left[ \quad \right]_1^2$  indicates limits of integration.

The results were actually not very sensitive to the limits. As Table 4.1 shows, integrating between three sets of limits did not change the value of the calculated condensate angle,  $\theta_c$ , by more than  $2^\circ$ ; and all results were reasonably close to the observed one, with the limits  $z^+ = 0.5$  to  $z^+ = 1$  giving the best value.

The method developed here also lends itself to a simple optimizing procedure to find the slope with the highest heat transfer rate. It has been shown that the heat transfer coefficient varies as  $\left[ \int_0^\phi \sin^{1/3} \phi \, d\phi \right]^{3/4}$  and as  $\cos^{1/4}(\sin^{-1} \sigma)$ . Therefore, when  $\sigma$  is plotted against  $\phi$  (or  $\theta_c$ ), the scale for  $\phi$  can be also marked for the values of the first function, and the scale for  $\sigma$  for the values of the second. The optimizing procedure becomes simply a matter of plotting  $\sigma$ , then finding the point along the curve for which the product

$$\cos^{1/4}(\sin^{-1} \sigma) \left[ \int_0^\phi \sin^{1/3} \phi \, d\phi \right]^{3/4} \quad (4.44)$$

is maximum. Such a chart is shown in Figure 4.2 with the  $\sigma$  curve plotted for Run No. 119.

For the horizontal position Table 4.2 shows a comparison of the values of  $\phi$  for test runs with various flow rates. These values were computed by integrating step-by-step starting from a known depth at the outlet end. The agreement between measured and calculated angles is only fair, but the obtained mean values for  $\phi$  over the length of the tube are still satisfactory for use in the heat transfer calculations, due to the insensitiveness of relation (4.44) to variations of  $\phi$  in the

range considered. The step-by-step integration of equation (4.42) involves small differences of the angle function on the left hand side. Consequently, errors in estimating the friction factors influence these calculations rather strongly, and the discrepancies found are not surprising.

Heat Conduction Through the Axially Flowing Condensate on the Bottom of the Horizontal Tube

So far only heat transfer through the thin condensate layer on the walls of the tube has been considered. To complete the investigation, heat transfer through the axially flowing condensate on the bottom must also be evaluated. It was shown previously that at least the upstream portion of this condensate flow must be laminar since the liquid velocities increase from zero at the entrance end. If the flow is laminar and secondary flows are neglected, then heat will be transferred across this condensate by conduction only. The geometry of the cross section is shown in Figure 3.2, with an enlarged view of the corner A shown. For the sake of obtaining a well-defined boundary, it is assumed that the bottom condensate and the film meet at an angle as shown. The thermal boundary conditions may be assumed to be uniform saturation temperature,  $t_s$ , at the interface, and uniform wall temperature,  $t_w$ . In order to further simplify the solution, it may be assumed that the variations of condensate depth along the tube are gradual enough to be neglected at any particular cross-section. Thus, the governing equation can be simplified into Laplace's equation for heat conduction in two dimensions.

$$\nabla^2 t = 0 \text{ or in cylindrical coordinates}$$

$$\frac{\partial^2 t}{\partial r^2} + \frac{1}{r} \frac{\partial t}{\partial r} + \frac{1}{r^2} \frac{\partial^2 t}{\partial \theta^2} = 0 \quad (4.45)$$

The boundary conditions are:

$$\text{at } r = r_o \quad t = t_w \quad (4.46)$$

$$\text{at } r \cos \theta = r_o \cos \theta_c \quad t = t_s \quad \text{to the edge of the film} \quad (4.47)$$

In this form the problem becomes one of pure conduction. The particular configuration involved suggests a solution by conformal mapping. The equation of the tube circle in the x-y coordinate system shown is

$$\begin{aligned} x^2 + (y + r_0 \cos \theta_c)^2 &= r_0^2 \\ x^2 + y^2 + 2yr_0 \cos \theta_c &= r_0^2 \sin^2 \theta_c \end{aligned} \quad (4-48)$$

Dividing by  $r_0^2 \sin^2 \theta_c$ , and defining  $X \equiv x/r_0 \sin \theta_c$  and  $Y \equiv y/r_0 \sin \theta_c$  yields:

$$X^2 + Y^2 + 2Y \cot \theta_c = 1$$

The moon-shaped cross-section ABCDEF of the bottom condensate may be mapped into the infinite slab A'B'C'D'E'F' shown in Figure 3.2b by using the complex transformation equation:

$$w = \ln \frac{z-1}{z+1}$$

where  $w = u + iv$  and  $z = X + iY$ . Consequently,

$$w = \ln \frac{X-1+iY}{X+1+iY}$$

Multiplying both the numerator and denominator by  $X+1-iY$  and simplifying yields:

$$w = \ln \left[ \frac{X^2 + Y^2 - 1}{(X+1)^2 + Y^2} + i \frac{2Y}{(X+1)^2 + Y^2} \right]$$

Since  $w = u + iv$ ,

$$e^{u+iv} = e^u (\cos v + i \sin v) = \frac{X^2 + Y^2 - 1}{(X+1)^2 + Y^2} + i \frac{2Y}{(X+1)^2 + Y^2}$$

Consequently,

$$e^u \cos v = \frac{X^2 + Y^2 - 1}{(X+1)^2 + Y^2} \quad \text{and} \quad e^u \sin v = \frac{2Y}{(X+1)^2 + Y^2}$$

$$\tan v = \frac{2Y}{X^2 + Y^2 - 1} \quad (4.49)$$

The temperature distribution in the complex  $u-v$  plane is linear between  $t_w$  along  $A'B'C'$  and  $t_s$  along  $B'E'F'$ . Mathematically:

$$\frac{t - t_w}{\Delta t} = \frac{v - \phi}{\pi - \phi} \quad \text{or} \quad t^+ = \frac{v - \phi}{\pi - \phi} \quad (4.50)$$

Substituting the value of  $v$  from equation (4.49) gives the temperature distribution in the  $X-Y$  plane:

$$t^+ = \frac{\tan^{-1} \frac{2Y}{X^2 + Y^2 - 1} - \phi}{\pi - \phi} \quad (4.51)$$

The heat transfer through the condensate may be computed from:

$$\frac{q'}{L} = \int k_c \left[ -\frac{\partial t}{\partial y} \right]_{y=0} dx$$

$$= \left( r_0 \sin \phi - \frac{y_{s0}}{\sin \phi} \right) - \left( r_0 \sin \phi - \frac{y_{s0}}{\sin \phi} \right)$$

where  $q'$  - heat transferred through bottom condensate, Btu/sec.

Substituting the dimensionless relations and using equation (4.51)

yields:

$$\begin{aligned}
 & \left(1 - \frac{\gamma_{so}}{r_0 \sin^2 \phi}\right) \\
 \frac{q'}{L} &= \int k_e \Delta t \left[ \frac{1}{\pi - \phi} \left( \frac{2}{1 - X^2} \right) \right] dX \\
 & - \left(1 - \frac{\gamma_{so}}{r_0 \sin^2 \phi}\right) \\
 &= \frac{2k_e \Delta t}{\pi - \phi} \cdot \frac{1}{2} \ln \left| \frac{1+X}{1-X} \right| \left(1 - \frac{\gamma_{so}}{r_0 \sin^2 \phi}\right) \\
 & \quad - \left(1 - \frac{\gamma_{so}}{r_0 \sin^2 \phi}\right) \\
 &= \frac{2k_e \Delta t}{\pi - \phi} \ln \left[ \frac{2r_0 \sin^2 \phi}{\gamma_{so}} - 1 \right] \\
 &= \frac{2k_e \Delta t}{\pi - \phi} \ln \left[ \frac{d_0 \sin^2 \phi}{\gamma_{so}} - 1 \right]
 \end{aligned} \tag{4.52}$$

Comparison of Heat Fluxes through the Bottom Condensate and through the Film on the Tube Walls

The heat flux per unit length through the condensing film may be computed from equation (3.18) with the constants taken as  $A = 3$ ,  $B = 6/5$ ,  $C = 0.68$ , and  $D = 1$ .

$$\begin{aligned} \frac{q}{L} &= \left( \overline{Nu}_o \frac{k_e}{r_o} \right) (2\phi r_o) \Delta t \\ &= \frac{2(4)^{\frac{3}{4}}}{3} \left[ \frac{g\rho_e(\rho_e - \rho_w)\lambda(1+0.689)k_e^3}{\mu_e} \right]^{\frac{1}{4}} \left[ \int_0^\phi \sin^{\frac{1}{3}}\phi d\phi \right]^{\frac{3}{4}} \left[ r_o \Delta t \right]^{\frac{3}{4}} \end{aligned} \quad (4.53)$$

Dividing equation (4.52) by (4.53) yields:

$$\frac{q'}{q} = 1.060 \left[ \frac{\mu_e k_e \Delta t}{g\rho_e(\rho_e - \rho_w)\lambda(1+0.689)r_o^3} \right]^{\frac{1}{4}} \frac{\ln \left[ \frac{d_o \sin^2\phi}{\gamma_{so}} - 1 \right]}{(\pi - \phi) \left[ \int_0^\phi \sin^{\frac{1}{3}}\phi d\phi \right]^{\frac{3}{4}}} \quad (4.54)$$

From equations (3.6), (3.9), and (3.17), with the same constants as given before equation (4.53), and setting  $X = \phi$

$$\begin{aligned} \frac{d_o}{\gamma_{so}} &= \frac{2r_o \rho_e \lambda (1+0.689)}{k_e \Delta t} \cdot \frac{df}{dx} \\ &= \frac{\sqrt{2} \sin^{\frac{1}{3}}\phi}{\left[ \int_0^\phi \sin^{\frac{1}{3}}\phi d\phi \right]^{\frac{1}{4}}} \left[ \frac{g\rho_e(\rho_e - \rho_w)\lambda(1+0.689)r_o^3}{\mu_e k_e \Delta t} \right]^{\frac{1}{4}} \end{aligned} \quad (4.55)$$

The ratio of heat fluxes, then, depends on the fluid properties, the quantity  $\left[ \Delta t / r_o^3 (1 + 0.68 S) \right]^{1/4}$ , and the depth of the bottom condensate expressed in terms of the central half-angle  $\phi$ . Figure 4.4 shows that this ratio is always very small for such vapor velocities where the bottom condensate still exists as a distinctly separate flow regime. For the highest flow rates encountered in the experiments with Refrigerant-113, the heat loss through the bottom condensate in a horizontal tube was about 2.5% of the heat transmitted through the condensate film on the wall according to these estimates. Turbulence of any sort in the liquid will increase this ratio, but these calculations show that the bottom condensate effectively insulates part of the condenser tube. The ratio expressed by equation (4.54) goes through a maximum near  $\phi = 170^\circ$  because the theoretical film thickness goes to infinity as  $\phi$  approaches  $180^\circ$ , and the assumed geometry cannot be satisfied near this point.

One more comment is in order here. For the above calculations a sharp angle was assumed to exist where the condensate film on the wall meets the liquid flowing on the bottom of the tube. Physically this situation is impossible. A smooth surface profile connecting the two flow regimes increases the liquid thickness in this vicinity where most of the heat transfer through the bottom condensate occurs. Consequently, the actual heat transfer becomes even less than predicted by the above relations.

## CHAPTER V

### INTERACTIONS BETWEEN PHASES

#### General Considerations

Due to shear at the interfaces and the geometrical restrictions imposed by the tube, the flow patterns of the two phases are strongly interrelated. The liquid collecting in the tube restricts the vapor flow area. Waves generated at the surface increase the effective shear stress and cause an additional pressure drop in the vapor phase. On the other hand, the high velocity vapor flow draws the liquid along and causes surface instabilities. If the vapor enters the tube at a downward angle instead of axially, the bottom condensate layer will be lowered by the momentum of the incoming stream. Vapor shear was taken into account in the previous Chapter to determine the depth of the bottom condensate. Surface waves have insignificant effect on the heat transfer since the liquid acts as an effective insulator and the vapor pressure drop is negligible. However, the thin layer of wall condensate might be seriously affected by the vapor drag, especially near the entrance region. To investigate the magnitude of this phenomenon, a simple analysis was developed. Instabilities of the interface were not considered at all. The liquid film was treated as laminar everywhere, and the vapor was assumed to flow axially.

Another effect arising from the presence of two phases is surface tension. It influenced the flow pattern of the liquid primarily in two ways. First and foremost it prevented the axially flowing condensate from breaking away at the outlet into a so-called free nappe; and, consequently, raised the surface above that predicted by the

critical depth theory. A rough order of magnitude estimate was developed for the maximum flow rate above which this effect becomes negligible. A second, rather insignificant, effect of surface tension was the smooth transition of the free surfaces where the wall condensate met the liquid flowing axially on the bottom. As it was found before, most of the heat transfer through the bottom condensate occurred near this region; and, consequently, this effect reduced this heat transfer rate considerably, while the wall condensate heat transfer was not influenced very much.

The Effect of Shear on the Condensate Film in a Horizontal Tube

Consider the flow of condensate on the walls of the horizontal tube. Due to gravity, the condensate will tend to flow downward and collect on the bottom of the tube. The axially flowing vapor, however, will tend to drag the liquid along due to the shear stress at the interface. Since the liquid layer is very thin compared to the tube radius, the curvature of the wall may be neglected. As a good first approximation momentum changes may also be ignored. Then the force balance for a small control volume,  $(y_s - y)r_o d\phi dz$ , can be written as follows.

In the  $\phi$  direction:

$$g(\rho_l - \rho_v) \sin \phi (y_s - y) r_o d\phi dz - \mu \frac{\partial u}{\partial y} r_o d\phi dz = 0 \quad (5.1)$$

which can be integrated to find the velocity distribution and the mean velocity,  $u_a$

$$u = \frac{g(\rho_l - \rho_v) \sin \phi}{\mu_l} \left( y_s y - \frac{y^2}{2} \right) \quad (5.2)$$

$$u_a = \frac{g(\rho_l - \rho_v) \sin \phi}{3\mu_l} y_s^2 \quad (5.3)$$

In the axial, z direction:

$$\tau_w r_o d\phi dz - \mu_l \frac{\partial \omega}{\partial y} r_o d\phi dz = 0 \quad (5.4)$$

which can be integrated to obtain,

$$\omega = \frac{\tau_w}{\mu_l} y \quad (5.5)$$

$$\omega_a = \frac{\tau_w}{2\mu_l} y_s \quad (5.6)$$

where  $w$  is the velocity in z direction.

For laminar flow of the condensate, heat transfer is by conduction only and the temperature distribution may be assumed to be linear.

Then the energy balance for an element  $y_s r_o d\phi dz$  becomes:

$$\lambda(1+0.683) d\Gamma_c = k_l \frac{\Delta t}{y_s} r_o d\phi dz \quad (5.7)$$

where  $\Gamma_c = Q_c \rho_l$ , mass flow rate of condensate.

The mass flow rate may be expressed in terms of velocities.

$$d\Gamma_c = \frac{\partial(\rho_l u_a y_s dz)}{\partial \phi} d\phi + \frac{\partial(\rho_l \omega_a y_s r_o d\phi)}{\partial z} dz \quad (5.8)$$

Substituting equations (5.3), (5.6), and (5.8) into (5.7) yields:

$$\frac{g\rho_l(\rho_l-\rho_v)}{3\mu_l r_0} y_s \frac{\partial(y_s^3 \sin\phi)}{\partial\phi} + \frac{\rho_l}{2\mu_l} y_s \frac{\partial(y_s^2 \tau_w)}{\partial z} = \frac{k_l \Delta t}{\lambda'} \quad (5.9)$$

where  $\lambda' = (1 + 0.68 \frac{c_p \Delta t}{\lambda})$

The boundary conditions may be selected by careful examination of the flow. At the entrance of the tube an initial condensate layer thickness may be prescribed. For example, if the vapor flow can be assumed to be axial at the entrance, then a zero initial thickness may be considered. The flow must be symmetrical with respect to the vertical through the center of the tube. From the physical standpoint the thickness is finite at the top of the tube and the liquid surface continuous. It must be realized, however, that certain mathematical solutions might not be able to conform with these last two requirements. The vapor shear stress,  $\tau_v$ , depends on the mass flow rate and, consequently, on  $z$ ; but it may be assumed to be independent of  $\phi$ , the angular position. The temperature difference,  $\Delta t$ , may be taken as constant.

#### Numerical Solution

Expanding equation (5.9) results:

$$\frac{g\rho_l(\rho_l-\rho_v)}{3\mu_l r_0} \left( \sin\phi y_s \frac{\partial y_s^3}{\partial\phi} + y_s^4 \cos\phi \right) + \frac{\rho_l}{3\mu_l} \tau_w \frac{\partial y_s^3}{\partial z} + \frac{\rho_l}{2\mu_l} y_s^3 \frac{d\tau_w}{dz} = \frac{k_l \Delta t}{\lambda'} \quad (5.10)$$

Substituting  $\bar{p} = y_s^3$  and rearranging yields,

$$\frac{\partial \bar{p}}{\partial z} = \frac{1}{\tau_w} \left[ \frac{3\mu_e k_e \Delta t}{\rho_e \lambda'} - \frac{g(\rho_l - \rho_v)}{r_0} \left( \sin \phi \bar{p}^{\frac{1}{3}} \frac{\partial \bar{p}}{\partial \phi} + \right. \right. \\ \left. \left. + \bar{p}^{\frac{4}{3}} \cos \phi \right) - \frac{3}{2} \bar{p} \frac{\partial \tau_w}{\partial z} \right] \quad (5.11)$$

The shear stress may be expressed as a function of the Reynolds number or the mass flow rate in the following form (Equations 4.31, 4.32, 4.33)

$$\tau_w = \frac{d_{hv}^{b_i}}{2\rho_v \mu_v^{b_i} A_v^{2+b_i}} a_i \Gamma_v^{2+b_i} \quad (5.12)$$

$$\frac{\partial \tau_w}{\partial z} = \frac{d_{hv}^{b_i}}{2\rho_v \mu_v^{b_i} A_v^{2+b_i}} a_i (2+b_i) \Gamma_v^{1+b_i} \frac{d\Gamma_v}{dz} \quad (5.13)$$

where the subscript ( )<sub>v</sub> refers to the vapor phase of the flow

$d_h$  hydraulic diameter, ft

$a_i, b_i$  constants depending on the range of the Reynolds number

Since at any cross section

$$\Gamma_l + \Gamma_v = \Gamma_{\text{inlet}} \text{ a constant}$$

$$d\Gamma_l = -d\Gamma_v \quad (5.14)$$

From equations (5.14) and (5.7)

$$\frac{\partial \Gamma_l}{\partial z} = - \frac{2k_e \Delta t}{\lambda'} \int_0^\phi \frac{r_0}{y_s} d\phi \quad (5.15)$$

For a numerical solution equations (5.11), (5.12), (5.13), and (5.15) can be written in finite difference form. Since  $\bar{p}_0$  at  $z = 0$  is known,  $\bar{p}_1$  at a small distance  $\Delta z$  away can be calculated. The procedure can be repeated until the end of the tube is reached or  $\Gamma_v$  becomes zero. Care has to be taken in the selection of points, since the thickness tends to infinity at the top of the tube at the outlet end.

In finite difference form the governing equations can be written as follows:

$$\Delta \bar{p}_n = \frac{\Delta z}{\tau_0} \left[ \frac{3\mu_e k_e \Delta t}{\rho_e \lambda'} - \frac{g(\rho_l - \rho_v)}{r_0} \left\{ \sin \phi \bar{p}_n^{\frac{1}{3}} \left( \frac{\partial \bar{p}}{\partial \phi} \right)_n + \bar{p}_n^{\frac{4}{3}} \cos \phi \right\} - \frac{3}{2} \bar{p}_n \frac{\partial \tau_0}{\partial z} \right] \quad (5.11a)$$

$$\begin{aligned} \left( \frac{\partial \bar{p}}{\partial \phi} \right)_n &= \frac{1}{2\Delta\phi} (3\bar{p}_n - 4\bar{p}_{n-1} + \bar{p}_{n-2}), \quad n \geq 3 \\ &= \frac{-1}{2\Delta\phi} (3\bar{p}_n - 4\bar{p}_{n+1} + \bar{p}_{n+2}), \quad n = 1, 2 \end{aligned} \quad (5.14 \text{ a \& b})$$

$$\frac{d\Gamma_v}{dz} = -\frac{2k_e \Delta t}{\lambda'} \sum_{n=1}^m \frac{r_0 \Delta\phi}{\bar{p}_n^{\frac{1}{3}}} \quad (5.15a)$$

Equations (5.12) and (5.13) remain the same.

Since the computer could not start with  $\bar{p}_0 = 0$ , several small thicknesses were assumed for the first value of  $\bar{p}$ . The magnitude of these were determined as arbitrary fractions of the thickness at the top of the round tube without shear; that is,

$$\gamma_{si} = K_4 \sqrt{\frac{3\mu_e k_e r_0 \Delta t}{g\rho_l(\rho_l - \rho_v)\lambda'}} \quad (5.16)$$

where  $K$  is an arbitrary constant.

The bottom condensate depth was assumed to be constant at  $\phi_c = 120^\circ$ . The fluid properties used were those of Refrigerant-113, and the tube radius taken was that of the experimental condenser. In order to avoid time consuming trial and error procedures, the tube length was not specified. Instead the entering vapor flow rate was given and the corresponding tube length could be determined from the calculations.

Flow rates were varied from  $0.2 \times 10^{-4}$  to  $4.3 \times 10^{-4}$  lbf sec/ft or slugs/sec; temperature differences were from 2 to 25 °F; and the increments were taken as  $r/10$  and  $3^\circ$ ,  $r/20$  and  $2^\circ$ .

The results showed that even for flow rates and temperature differences considerably higher than the ones encountered in the experiments, the film thickness reached essentially the same value as predicted by the no-shear theory in less than three radius lengths along the tube. Consequently shear has negligible effects as far as the thinning out of the condensate film is concerned. The experimental observations, however, indicated that the film had a wavy surface at the entrance of the tube at the highest flow rates. Such an instability problem was, of course, not included in the above analysis.

The numerical solutions became unstable after the thickness reached the no-shear values; and, consequently, the calculations could not be continued to the end of the tube. The purpose of this analysis, namely the estimate of the effect of shear near the entrance, was, however, fulfilled. A typical set of surface profiles are shown in Figure 5.1.

Estimate of Transition Flow Rate for Surface Tension Effects

An order of magnitude estimate may be made of the minimum flow rate below which the nappe cannot break away by considering the minimum momentum required to balance the surface tension of the solid liquid boundary formed as the nappe springs free. If uniform velocity distribution is assumed, the momentum of the flow in the horizontal direction is,

$$\rho_l V_m^2 A_s = \rho_l \frac{Q_l^2}{A_l} \quad (5.16)$$

The horizontal component of the surface tension at the lip of the tube outlet is:

$$P_w \sigma_{l0} \sin \gamma \quad (5.17)$$

where  $P_w$  wetted tube perimeter, ft

$\sigma_{l0}$  surface tension of liquid film, lbf/ft

$\gamma$  contact angle

Equating the two expressions yields:

$$Q_l^2 = \frac{P_w A_l \sigma_{l0} \sin \gamma}{\rho_l}$$

or in dimensionless form for a round tube:

$$\frac{Q_l}{\sqrt{g r_0^5}} = \sqrt{\frac{2 \theta_c (\theta_c - \sin \theta_c \cos \theta_c) \sigma_{l0} \sin \gamma}{g \rho_l r_0^2}} \quad (5.18)$$

For the water-plastic combination a contact angle of approximately  $45^\circ$  was measured. The resultant flow rate is, assuming  $\theta_c = 45^\circ$ , and

taking  $\sigma_w = 4.93 \times 10^{-3}$  lbf/ft corresponding to the approximate water temperature used of 80 °F,

$$\frac{Q_c}{\sqrt{gr_0^3}} = 0.1113$$

For the Refrigerant-113 and copper combination a contact angle of 50°\*, taking  $\theta_c = 45^\circ$  and  $\sigma_w = 1.302 \times 10^{-3}$  lbf/ft, yields,

$$\frac{Q_c}{\sqrt{gr_0^3}} = 0.0914$$

These flow rates are both in the regime where the observed outlet depths begin to deviate from the critical depths predicted by the theory, and where the above effect became noticeable in the experiments with water.

CHAPTER VI  
THE EXPERIMENTAL WORK

Fluid Mechanics Analogy Experiments

It was recognized at the beginning of this work that one of the weak points of previous analyses was the determination of the depth of the axially flowing condensate. The first part of the experiments was set up in order to gain more insight into the problem of a liquid flowing along a horizontal tube with the flow rate varying along the length of the tube. The importance of the outlet end conditions has been pointed out before. In these experiments special attention was given to the flow conditions existing in this region.

Description of the Apparatus

The apparatus is shown in Figures 6-1 and 6-2, and schematically in Figure 6-3. The test section consisted of a transparent plastic tube 54 inches long with an internal diameter of 1.10 inches. At twelve points along the tube, equally spaced at 4.5 inches, means were provided for admitting liquid on both sides and for letting vapor or air out at the top. This arrangement is shown in Figure 6-4. Liquid was supplied to these points from a distributor which also served as a flow-rate measuring device for each supply point. The flow rates were determined on the Venturi principle by measuring the liquid static pressure differential between the top of the distributor block and in the small stainless steel tubes through which the fluid had to flow to reach the test section. These pressure differences were read on manometers. The flow rates could be adjusted by small needle valves. The distributor chamber on top of the

distributor block housed a metal and a cloth filter, and it had a valve on top which served both as a flow regulator and air bleed. This valve was connected to a line which returned the excess liquid to the collecting tank at the outlet of the test section. From this tank a small Monel Metal pump circulated the fluid through a standard commercial filter back into the distributor. Although means were provided for supplying air at the entrance of the test section, and for bleeding it off at twelve points along the tube, this part of the setup was not utilized. During the first trials it was discovered that the ripples caused by the fluid streams entering at the supply points were large enough to be "caught" by very low flows of air. The ensuing wave pattern could not be expected to be similar to the one occurring during a condensation process. Since in the second phase of the experiments the actual condensation flow patterns were to be observed, the analogy studies with a high vapor shear stress were abandoned. Thus the first phase of the experimental work endeavored primarily to establish flow depths near the end of the horizontal tube and to find the critical Reynolds numbers at which transition from laminar to turbulent flow occurs. These experiments were performed using distilled water as the fluid. This setup could not be used effectively for inclined tube experiments because in supercritical flows the liquid streams entering at the twelve supply points generated strong, oblique standing waves that made any depth measurement meaningless.

#### Experimental Procedure.

After the pump was started, the flow rates were adjusted at the supply points to the desired quantities. The overall flow rate was controlled by either varying the pump speed, or by regulating the valves at

the pump outlet or at the distributor bleed. It was found that for the required flow rates the pump worked steadiest at a relatively low speed. Thus, most of the controlling was achieved by the valves with the pump running at the optimum. The flow rates to the individual supply points were regulated by the small needle valves mentioned before. After equilibrium was reached, the total volume flow rate was measured at the tube outlet with a graduate and a stop watch. The depth of the flow at any point was established by wrapping a strip of paper around the tube, and marking both the circumference and the points where the surface of the liquid met the walls, viewed diagonally across the tube. The temperature of the liquid was measured by a mercury-in-glass thermometer graduated in increments of 0.2 °F. Turbulence was determined by injecting ink axially into the stream through a small stainless steel syringe.

#### Condensation Experiments

Since very little experimental data was available in the literature that could be used directly to check the validity of the analysis, it became clear that an experimental setup was needed to furnish heat transfer data. In addition, it was deemed important that the apparatus should also furnish some information on the flow conditions existing in the tube. Refrigerant 113 ( $C_2Cl_3F_3$ ) was chosen as the fluid because of its favorable pressure-temperature relationships.

#### Description of the Apparatus

The equipment is shown in Figures 6-5, 6-6, 6-7, and schematically in Figure 6-8. The vapor was generated in a 12 1/8" high boiler, made of 5 1/2" standard brass pipe, set on top of a 2000 watt flat plate heater. Inside the top of the boiler was a circular splash plate. A 7/8"

o.d. copper tube served as riser from the boiler. A heater wire wrapped around an insulated portion of the tube served as superheater. The vapor passed from the riser into the 1/2" o.d. entrance tube through a heat-resistant flexible hose. The entrance tube contained a stainless steel thermocouple well and the connection to the first mercury manometer. The entrance tube joined the top of the test section at an angle of approximately 45° to allow the installation of a glass reticle at the front end of the test section. This window served both for observation and for illumination of the interior of the equipment. The condenser section consisted of a 28.25 inch long 5/8" o.d. standard finned copper tube.

The condensed liquid was discharged into a 100 cc burette. This burette was sealed into the bottom leg of the copper tee into which the outlet end of the test section was soldered. The other two legs of the tee, one directly opposite to the outlet of the test section and one on top contained observation windows. The burette was sealed with two O-rings and several layers of Glyptal compound. The observation windows were glued to a brass bushing which was sealed in the tee by two O-rings. The tee also contained the mercury manometer connection, which also served as the purge line, the condensate outlet thermocouple, and a liquid overflow connection. At the bottom of the measuring burette a needle valve was installed to serve both as a flow regulator and a shut-off device for the measurements. The overflow line had a liquid seal at the top, to prevent the escape of any vapor, and a shut-off valve.

The liquid returned to a one liter capacity glass receiver through a 3/8" o.d. copper line. The receiver supplied the boiler through a short copper tubing which was connected to the charging valve too. All parts,

except the test section, the observation windows, and manometers, were insulated with glass wool insulation covered with aluminum foil. The burette insulation was divided into several sections which could be moved up and down to allow for readings to be taken at several intervals along the tube.

The electrical input to the heaters was regulated by two Variacs. The power was measured by a wattmeter connected to a switch box, which made it possible to measure the power going into both heaters with the same wattmeter.

Temperatures were measured at the entrance of the test section, at six points along the tube, at the outlet, and at any two other points as required. All thermocouples were made of No. 30 gauge copper-constantan thermocouple wires with the reference junctions kept in an iced thermos bottle. The inlet junction was housed in a stainless steel well located along the axis of the short inlet tube. The outlet junction was located right behind the lower edge of the test section. This junction was silver soldered protruding outside the stainless steel tubing through which the connections led to the outside. The location of this thermocouple forced at least part of the condensate to flow along the steel tube until it reached a splash guard which directed it into the measuring burette. The six thermocouples along the test section were soldered into grooves cut into the tube parallel to the fins. Three of these were located on the top, three at diametrically opposite points on the bottom. Four were one-sixth of the tube length from each end and two in the middle. The thermocouple wires were connected to a Leeds and Northrup semi-precision potentiometer through a ten-point selector switch.

The air velocities around the test section were controlled by two fans which were adjusted to provide a reasonably uniform flow distribution along the tube. The air velocities were measured with an Anemotherm Air Meter.

Photographs of the flow conditions inside the test tube were taken through the outlet observation window, while illumination was provided with a photographic flood light through the reticle at the entrance. Because of condensation on the reticle, pictures could not be taken through it, although visual observations were possible. A single-lens reflex camera was used with special lens attachments that provided closeup pictures at relatively restricted depth of focus. Thus the approximate location of the flow pattern picture could be determined. Visual measurements of the central angle subtended by the bottom condensate were also made with the aid of a glass reticle marked with diagonals  $30^\circ$  apart. To reduce the blow-out hazard, a power cut-off switch was installed at the top of the outlet manometer on the atmospheric side.

#### Experimental Procedure

The apparatus was placed in a constant temperature room. The system was evacuated, then it was charged with distilled Refrigerant 113. The test section was leveled by adjusting the four bolts on which the framework rested. An optical level was used to establish the horizontal position of the tube. To obtain any desired slope, up to about  $10^\circ$ , accurately machined steel blocks were placed under the two supporting bolts near the entrance of the test section. The following procedure was used for the test runs.

First the room temperature was established. In order to reduce the possibility of air leaking into the system, this temperature was set at such level that during the runs the system pressure always stayed above atmospheric pressure. This meant that for low flow rates of vapor higher room temperatures had to be used than for high flow rates. The air velocities around the condenser were checked next. The purge line vacuum pump was started; the main heater and, when necessary, the superheater were turned on and set at the required power level. For most runs the liquid overflow valve was kept closed, and the burette outlet needle valve was adjusted such that during equilibrium the burette was nearly full of liquid. This arrangement minimized the amount of condensation occurring outside the test section. After an initial warm-up period, the purge line was opened very slightly. The bleed flow rate was kept at a minimum by adjusting both a needle valve and a pinchcock on the vacuum line. After equilibrium was reached, data were taken in the following order, unless some special circumstances arose:

1. Barometric pressure
2. Mercury and refrigerant levels in the manometers
3. Thermocouple millivolt readings
4. Flow rates in the burette

## CHAPTER VII

DISCUSSION, CONCLUSIONS, AND RECOMMENDATIONSFOR FUTURE WORKDiscussion

The fluid mechanics analogy setup was built for the purpose of providing direct access for measurements on the liquid used. It could not fulfill all the requirements of a really close analogy to the condensation process, but it provided very useful quantitative and qualitative results that could not be obtained from a condensation experiment.

The data for these water analogy experiments are tabulated in Appendix III, Tables A-2 and A-3, for a range of flow rates of  $0.02 < Q_{lo}/\sqrt{gr_o^5} < 0.6$ . The results of flow depth measurements at the outlet of a horizontal tube are plotted in Figure 7.1 for both the fluid mechanics analogy and condensation experiments. The curves in the figure indicate the variation of critical depth as calculated from equation (4.16). The solid line, with  $\sqrt{\alpha/\beta} = 1$  may be used for the turbulent range,  $\overline{Re} > 3,000$ ; the dashed line, with  $\sqrt{\alpha/\beta} = 1.414$  is applicable to laminar flows,  $\overline{Re} < 3,000$ . The experimental points for both fluids agree well with the curves, down to a flow rate of about  $Q_{lo}/\sqrt{gr_o^5} = 0.08$ . Below this point, the measured flow depth remained essentially constant at  $\phi_c = 90^\circ$ , deviating from the theoretical curve. One, minor reason for this discrepancy is the fact that at lower flow rates the actual position of the critical depth moves closer to the outlet end of the tube where the surface profile varies rather rapidly. Thus the measurements, taken at an essentially fixed distance upstream from the end, would tend to

yield greater depths. Another, much more important reason is the increasing importance of the surface tension at the lower flow rates. It was observed during the experiments with water that while at high flow rates the liquid broke away horizontally from the end of the tube to form a free nappe, at low flow rates the liquid clung to the lower lip of the outlet and flowed downward and sometimes even slightly backward from the end of the tube. This flow pattern resulted in a sharp downward curvature of the surface profile. The forces due to surface tension became large enough to effectively dam up the flow and, together with the change in pressure distribution at the overflow, caused an increase in depth. Under such circumstances the relatively simple critical depth theory was unsatisfactory since it accounted only for gravity. An order of magnitude estimate of surface tension effects was discussed in Chapter V.

The estimated accuracy of the measurements was 3% for the flow rates and 3° for the subtended angles at the point of measurement approximately 1 1/2 diameter distance from the outlet end.

The fluid mechanics analogy experiments also allowed the determination of the critical Reynolds number where transition from laminar to turbulent flow occurs. These data are shown in Table A-3 of Appendix III. The critical Reynolds number was found to be 3,580 with a minimum of disturbances and 2,830 with strong disturbances near the measuring point at the outlet.

What the fluid mechanics analogy setup could not simulate was the effect of vapor shear and the proper flow pattern in the inclined position. Both of these shortcomings arose from the local disturbances caused by the

relatively concentrated liquid feeds. Even the smallest of air flows in the tube caught these local ripples and made the entire surface wavy. Consequently, it was considered meaningless to try to compare these flow patterns to the ones actually found in a condenser tube. When the tube was inclined and the flow became rather fast, these feed points generated comparatively large, standing oblique waves which made any depth measurements meaningless.

The condensation experiments provided a great deal of quantitative and qualitative information. The most important numerical results were the ones for condensate flow depths and heat transfer rates.

All these data are also tabulated in Appendix III, Tables A-5 and A-6. Flow rates varied in the range  $0.007 < Q_{\ell} / \sqrt{gr_0^5} < 0.2$ ; the slopes ranged from  $\sigma = 0$  to  $\sigma = 0.1736$ .

The outlet depth data for the horizontal position was discussed above, together with the water analogy data. The measured surface profiles in the horizontal position were compared to the calculated profiles in Chapter IV (p. 65), and representative values were shown in Table 4.2. The agreement was fairly good, provided that the actual outlet depth was used as the starting point for the step-by-step integration procedure. The data also indicate that the mean depth along the horizontal tube remained essentially constant for the entire range of flows at a value of  $\phi_{cm} = 120^\circ$ .

For the inclined positions, a marked decrease of depth was observed up to a slope of about 0.01; a further increase in slope decreased the depth rather slowly. The ranges of mean condensate angles observed for each inclination are summarized, together with the heat transfer data, in Figures 7.2a and 7.2b. These mean angles were compared to the results

calculated from equation (4.43) in Chapter IV, and comparative values were tabulated in Table 4.1. The agreement was considered good.

The measurements of the subtended angles are estimated to be within  $5^\circ$  of true values in the downstream portion and progressively worse upstream becoming probably about twice as much near the inlet. The flow rates are accurate to 3%.

The heat transfer data are presented in Figures 7.2a and 7.2b. The theoretical lines and experimental data correlate rather well. The increased heat transfer coefficients for the inclined tubes are clearly distinguishable. A few of the low points are mainly due to small quantities of air in the apparatus particularly at the flow rates where the inside pressure was nearly the same as the atmospheric. The greatest source of error in these measurements lies in the determination of the mean wall temperature and, consequently, the magnitude of the temperature difference. There was a strong variation of temperatures from the top to the bottom of the tube, although axial variations were small. The temperature deviated from 9 to 21% from the mean with the inclined tubes, particularly the one with the greatest slope, yielding the smaller values. The temperatures for the inlet vapor and the discharged condensate could be taken within  $0.2^\circ\text{F}$ , but the wall temperature fluctuations varied from practically zero at the low flow rates to  $1^\circ$  at the highest. Room temperature fluctuated within  $1.5^\circ$  of the mean. The accuracy of volumetric flow rates was about 2%. The heat transfer results are estimated to be within about 15% of true values.

The manometer readings indicated that the maximum pressure drop in the condenser tube was of the order of 5 mm Mercury. The two, independently mounted manometers did not allow accurate readings of

such small magnitudes.

Some qualitative observations do not show up in the results and will be discussed here. The biggest problem in performing the experiments with the condensation setup was to eliminate the effect of air in the system. In spite of the precautions taken small amounts of air always remained in the system, in part because the refrigerant contained some of it itself. Finally the purge line had to be installed at the outlet of the test section. The bleed was regulated at such a rate that the visual observations showed no reduction in the wall condensate film thickness. This change in thickness could be detected as a hardly noticeable ring at some cross section of the tube. By increasing the bleed rate such a ring could be made to travel to the downstream end of the tube and disappear. In order to eliminate the air from the liquid, it was allowed to boil for at least two hours before the first test of a day was started. In addition, the room temperature was kept at such a level that the system pressure was always above atmospheric. At the lower flow rates and pressure levels it was sometimes quite difficult to keep the aforementioned condensate ring at the outlet end of the tube, and a few of the data points are low quite probably because of this phenomenon.

The variation of wave patterns and ripples was very interesting to observe. In the horizontal position waves caused by the vapor shear on the bottom condensate appeared at relatively low flow rates. First they were only near the entrance region; then, with increased flow rates, they spread over the entire surface. These large shear waves, however, disappeared for the most part along the surface profiles as the tube was inclined. Instead, very tiny, oblique standing ripples occurred near

the walls; and at higher flow rates occasional large traveling gravity waves were generated near the point where the liquid ramp existing in the entrance region joined the rather uniform surface along the tube. While the shear waves were rather uniform and periodic with a size up to about one-quarter of the depth; the gravity waves appeared rather randomly, traveling all by themselves, and their size was comparable to the depth. These observations indicate, among other things, that the vapor pressure drop should be less in an inclined tube not only because the vapor cross-sectional area increases, but also because of the disappearance of shear waves.

At the very highest flow rates very strong disturbances were observed at the entrance. In the horizontal tube no distinguishable bottom condensate existed here. In the inclined tube ripples appeared on the wall. Once vapor shear becomes dominant, the analytical results based on the existence of a primarily gravity controlled free-surface flow cannot be used. It is recommended, therefore, that these results should not be applied above a vapor Reynolds number of about 35,000, which was approximately the highest value encountered in these experiments.

The surface profiles, when not considering the waves, were fairly uniform along the tube for most runs. In the horizontal tubes the greatest variations occurred near the outlet, and also at the entrance due to the momentum of the vapor stream. In the inclined position, except for the smallest inclinations, the flow formed a ramp at the entrance then continued rather uniformly to the end.

### Conclusions

Heat transfer rates for laminar condensation of a pure vapor in horizontal and inclined tubes can be predicted by the use of the methods presented. For fluids of Prandtl numbers greater than one, the first approximation of the momentum energy solution, equation (3.23), which is equivalent to Nusselt's results, can be employed for estimating film coefficients as a function of the condensate angle, with Rohsenow's (40) value of 0.68 used for  $C$ . For liquid metals, a correction factor from Figure 3.3 is needed, although there is no good experimental data available to check these curves. The depth of the bottom condensate can be established for horizontal or essentially subcritical flows by a step-by-step integration of equation (4.42) starting at the outlet. For horizontal tubes with a straight-cut discharge, the critical depth can be assumed to exist at the outlet if  $Q_{e0} / \sqrt{gr_0^5} > 0.08$ . For lower flow rates a constant outlet angle of  $\phi_c = 90^\circ$  can be used as shown in Figure 7.1. As a matter of fact, for fluids similar to Refrigerant-113, a constant mean depth of  $\phi_{cm} \approx 120^\circ$  may be assumed over the entire range up to  $Q_{e0} / \sqrt{gr_0^5} = 0.2$ . These methods will yield conservative figures if applied to a condenser tube with an elbow at the outlet.

For inclined tubes equation (4.43) together with equations (4.34) can be used (integrating from  $z^+ = 0.5$  to  $z^+ = 1$ ) for calculating

$$\theta_{cm} = \phi_{cm} / 2.$$

Chaddock (10) showed that a horizontal tube is better for heat transfer than a vertical one. The results of these investigations indicate that when condensation occurs inside a single-pass condenser tube, a slight downward slope will enhance heat transfer. The optimum

slope for a given flow rate can be estimated from equation (4.43) together with Figure 4.3, as described in Chapter IV. This relation is expected to yield good results even if there is an elbow at the outlet.

At high vapor flow rates above an entering vapor Reynolds number of about 35,000, these relations are no longer valid because gravity effects are negligible and the orientation of the tube becomes unimportant. In such a case, heat transfer data can be correlated in terms of a Reynolds number, irrespective of slope (2). Consequently, for condensation inside tubes, the horizontal and inclined positions are at no time worse than the vertical, and in most cases they are better. The only exception is the case of extremely short tube with a length-diameter ratio of less than about 6.

The following are brief descriptions of the calculating procedures to be used for predicting the performance of horizontal and inclined single pass condenser tubes. In each case the following quantities are specified: the entering vapor condition, the temperature differential between vapor and wall, the dimensions and slope of the tube.

For the horizontal tube two procedures may be used. The quicker and more approximate one is to assume a constant mean condensate angle of  $\phi_{cm} = 120^\circ$ . Consequently, with  $\phi = 180^\circ - (\phi_{cm}/2) = 120^\circ$ , the flow rate can be calculated by integrating equation (4.36); and the Nusselt number can be evaluated from equation (3.23) with  $C = 0.68$ . The more accurate method is to assume a  $\phi_{cm}$  and a corresponding  $\phi$ , calculate the flow rate as before, then from Figure 7.1 find an outlet depth corresponding to the flow rate there. Starting from this end calculate the surface profile by integrating equation (4.42) stepwise along the tube. Find the mean value of  $\phi$  over the length of the tube and compare it to the assumed

value. If the two are within 10% the agreement may be considered satisfactory; otherwise a new mean angle should be assumed and the procedure repeated. With the final value of  $\phi$ , the Nusselt number can be estimated from equation (3.23) as above.

For the inclined tube first assume a constant mean condensate angle  $\phi_{cm}$  and its corresponding  $\phi$ . Using  $\phi$ , calculate the constant change of flow rate,  $\Omega$ , from equation (4.36). Substitute this value into equation (4.43) and set the limits between  $z^+ = 0.5$  and  $z^+ = 1$ . Using the angle functions (based on equations (4.34)) tabulated in Appendix VI, find several values of  $\sigma$  corresponding to different assumed angles. Plot the  $\sigma - \phi$  curve, as shown in Figure 4.3, and find the angle  $\phi$  corresponding to the given slope. The agreement between this value of  $\phi$  and the originally assumed one should be within about 3° in this case. If it is not, assume a new value for  $\phi$  and repeat the procedure. With the final value of  $\phi$  and  $\Omega$ , the flow rate and the Nusselt number can be evaluated as before from equations (4.36) and (3.23), with the latter expression multiplied by  $\cos^{1/4}(\sin^{-1} \sigma)$ . Actually both this function, and the angle integral function appearing in (3.23) can be read off directly from the chart in Figure 4.3. To estimate the optimum slope for the given  $\Omega$ , find the point on the  $\sigma - \phi$  curve for which the product of the other two coordinates, relation (4.44), is maximum.

For both horizontal and inclined tubes, the entering vapor Reynolds number should be ascertained to be less than 35,000.

### Recommendations for Future Work

The many complex processes occurring during condensation inside a tube suggest a number of investigations, some of which would be highly practical while others might have only academic interest. Here a few of what seem to be the most important leads will be mentioned.

1. Experimental data is needed on liquid metals for checking the existing analyses.
2. The effect of superheat should be investigated in view of the newer theories predicting a lowering of heat transfer rates with high superheats.
3. Condensation experiments could be done with different outlet end conditions, particularly with elbows of different diameter to radius of curvature ratios, and with tubes of various length-diameter ratios.
4. The vapor flow inside a tube with a liquid occupying the bottom section could be investigated theoretically. Assuming laminar flow and neglecting liquid velocities, the flow pattern of the vapor may be calculated for different vapor-liquid cross-sectional area ratios. Then the boundary conditions found at the interface can be used to solve for the liquid velocity distribution.

5. The problem of condensation in a tube or channel with no gravity acting should be examined. Here the problem of how to move the condensate becomes important. One possibility to be explored is condensation on a porous wall through which the condensate is sucked at various rates.

6. Further experiments will be necessary with high vapor velocities to study the transition regime where gravity becomes unimportant.

In all of the experimental investigations visual observations should be considered extremely important to establish the exact flow conditions occurring.

## NOMENCLATURE

a	constant in boundary layer equations
$a_i$	constant in friction factor equations
$\bar{A}$	$\left. \frac{\partial u^+}{\partial y^+} \right _w$
$\bar{A}_{0,1, \dots}$	perturbation terms of A
A	cross sectional area of flow, ft <sup>2</sup>
$A_h$	heat transfer area, ft <sup>2</sup>
$A_e$	liquid cross sectional area, ft <sup>2</sup>
$A_v$	vapor cross sectional area, ft <sup>2</sup>
b	width of liquid surface, ft
$b_i$	exponent in friction factor equations
B	$\int_0^i u^{+2} dy^+$
$B_{0,1, \dots}$	constants in boundary layer equations
c	velocity of surface waves, ft/sec
$c_{pe}$	liquid specific heat, Btu-ft <sup>4</sup> /lbf-sec <sup>2</sup> -°F or Btu/slug-°F
C	$1 - \int_0^i u^{+t} dy^+$
$C_{0,1, \dots}$	perturbation terms of C
$C_v$	correction factor for velocity distribution
$d_{he}$	liquid hydraulic diameter, ft
$d_{hv}$	vapor hydraulic diameter, ft
$d_o$	diameter of tube, ft
D	$\left. \frac{\partial t^+}{\partial y^+} \right _w$
$D_{0,1, \dots}$	perturbation terms of D

- e base of natural logarithms
- $E_{0,1}, \dots$  quantities defined in boundary layer equations
- f  $u_a y_s$ , volumetric wall condensate flow rate per unit length, ft<sup>3</sup>/sec-ft
- $f_e$  liquid friction factor
- $f_v$  vapor friction factor
- F  $u_a y_s \left[ \frac{D^3 g (\rho_l - \rho_v) k_e^3 \Delta t^2 \ell^3}{F \mu_e \rho_e^3 \lambda^3 (1 + C_3)^3} \right]^{-1/4}$ , dimensionless flow rate
- $\overline{Fr}$   $\frac{Q_e}{A_e} \sqrt{\frac{b}{g A_e}} = \frac{Q_e}{Z \sqrt{g}}$ , Froude number
- g gravitational acceleration, ft/sec<sup>2</sup>
- $\overline{g}(y)$  function in boundary layer equations
- G(x)  $\frac{g(\rho_l - \rho_v) \sin \phi}{\rho_e}$ , variation of gravity in x direction, ft/sec<sup>2</sup>

- j(x) function in boundary layer equations
- J( $\eta$ ) function in boundary layer equations

$k_e$	thermal conductivity of liquid, Btu/sec-ft-°F
$K$	constant
$\kappa$	$\frac{k_e \Delta t D}{\mu_e \lambda (1 + C_S)}$
$\ell$	characteristic length, ft
$L$	length of tube, ft
$m$	exponent
$n$	exponent
$N(x)$	function in boundary layer equations
$Nu$	$\frac{h_m \ell}{k}$ , $\frac{h_r r_o}{k}$ , Nusselt number
$\overline{Nu}$	mean Nusselt number based on arc $\phi$
$\overline{\overline{Nu}}$	mean Nusselt number based on total circumference, $\phi = \pi$
$p$	pressure, lbf/ft <sup>2</sup>
$\overline{p}$	$y_s^3$
$P_v$	$r_o(\phi + \sin \phi)$ , vapor wetted perimeter, ft
$P_w$	$r_o \phi_c$ , liquid wetted perimeter, ft
$\overline{Pr}$	$\frac{c_p \mu_e}{k}$ , Prandtl number
$q$	heat flow through wall condensate, Btu/sec
$q'$	heat flow through bottom condensate, Btu/sec
$q''$	volumetric liquid flow rate per unit width of channel, ft <sup>3</sup> /sec-ft
$Q$	volumetric flow rate, ft <sup>3</sup> /sec
$Q_\ell$	liquid volumetric flow rate, ft <sup>3</sup> /sec
$Q_{\ell o}$	liquid volumetric flow rate at outlet of tube, ft <sup>3</sup> /sec
$Q_v$	vapor volumetric flow rate, ft <sup>3</sup> /sec

$r$	radial distance, ft
$r_o$	radius of tube, ft
$r_{he}$	$\frac{A_l}{P_w}$ , hydraulic radius of liquid, ft
$r_{hv}$	$\frac{A_v}{P_v}$ , hydraulic radius of vapor, ft
$\overline{Re}$	$\frac{4\rho Q}{\mu P}$ , Reynolds number
$\overline{Re}_l$	$\frac{4\rho_l Q_l}{\mu_l P_w}$ , liquid Reynolds number
$\overline{Re}_v$	$\frac{4\rho_v Q_v}{\mu_v P_v}$ , vapor Reynolds number
$s$	elevation, ft
$s_o$	elevation of channel bottom, ft
$s_c$	depth of centroid of $A_l$ below surface, ft
$t$	temperature, °F
$t_s$	saturated vapor and condensate surface temperature, °F
$t_w$	wall temperature, °F
$\Delta t$	$t_s - t_w$
$t^+$	$\frac{t - t_w}{\Delta t}$
$T(\eta)$	$\frac{t_s - t}{\Delta t}$
$u$	velocity in x direction, ft/sec; except in complex transformation of bottom condensate cross section where
$u$	coordinate in complex u-v plane
$u_a$	$\frac{1}{y_s} \int_0^{y_s} u dy$ , mean velocity, ft/sec
$u^+$	$u/u_a$

$u$	velocity in y direction, ft/sec
$v$	coordinate in complex plane
$V$	velocity, ft/sec
$V_c$	critical velocity, ft/sec
$V_m$	mean velocity, ft/sec
$w$	velocity in z direction, ft/sec
$w$	$u + iv$ , complex variable
$x$	distance, ft
$X$	dimensionless distance in      direction
$y$	distance, ft
$y_s$	wall condensate film thickness, ft
$y_{so}$	wall condensate film thickness at surface of bottom flow, ft
$y_\infty$	$y$ at $\infty$
$y^+$	$y/y_s$
$Y$	dimensionless distance in y direction
$Y_{1,2, \dots}$	quantities defined in equation (3.38)
$z$	distance in axial direction, ft
$z^+$	$z/L$ , dimensionless distance in z direction
$Z$	$A_e \sqrt{\frac{A_e}{b}} = r_o^{2.5} (\phi_c - \sin \phi_c)^{\frac{3}{2}} / 4 \sqrt{\sin \phi_c / 2}$ , section factor, $\text{ft}^{2.5}$

Greek Letters

$\alpha$	$\frac{1}{AV_m^3} \int_A v^3 dA$ , velocity correction
$\alpha_t$	$\frac{k_e}{c_{pe} \rho_e}$ , thermal diffusivity, ft <sup>2</sup> /sec
$\beta$	$\frac{1}{Qh} \int_A \left( \frac{p}{\rho g} + s \right) V dA$ , pressure correction
$\gamma$	contact angle
$\Gamma$	mass flow rate, slugs/sec
$\Gamma_{in}$	total mass flow rate in tube, slugs/sec
$\Gamma_e$	liquid mass flow rate, slugs/sec
$\Gamma_v$	vapor mass flow rate, slugs/sec
$\epsilon$	$\frac{BDk_e \Delta t}{A\mu_e \lambda (1 + C\beta)}$
$\zeta$	$\frac{c_{pe} \Delta t}{\lambda}$ , dimensionless temperature difference
$\eta(x,y)$	transform variable for boundary layer equations
$\eta_s$	$\eta$ at $y_s$
$\theta$	angle in condensate
$\theta_c$	$\phi_c/2$ , condensate subtended half angle
$\lambda$	latent heat of vaporization, Btu-ft <sup>4</sup> /lbf-sec <sup>2</sup> or Btu/slug
$\lambda'$	$\lambda (1 + C\zeta)$ , generally $C = 0.68$
$\mu$	viscosity, lbf-sec/ft <sup>2</sup>
$\mu_e$	liquid viscosity, lbf-sec/ft <sup>2</sup>
$\mu_v$	vapor viscosity, lbf-sec/ft <sup>2</sup>
$\nu$	kinematic viscosity, ft <sup>2</sup> /sec
$\xi$	time, sec

$\rho_l$	liquid mass density, lbf-sec <sup>2</sup> /ft <sup>4</sup> or slugs/ft <sup>3</sup>
$\rho_v$	vapor mass density, lbf-sec <sup>2</sup> /ft <sup>4</sup> or slugs/ft <sup>3</sup>
$\sigma$	$\frac{ds_o}{dz}$ , slope
$\sigma_{lv}$	surface tension, lbf/ft
$\tau_s$	vapor shear stress at interface, lbf/ft <sup>2</sup>
$\tau_w$	liquid shear stress on walls, lbf/ft <sup>2</sup>
$\phi$	surface inclination to horizontal. For round tube it is the angle from top of tube to a point on wall
$\phi_c$	$2\theta_c$ , central angle subtended by bottom condensate stream function
$\Omega$	$dQ_c/dz$ , axial rate of change of condensate flow, ft <sup>3</sup> /sec-ft

Subscripts and Superscripts not Defined in Nomenclature

APPENDIX I

DETERMINATION OF THE INTERFACE BOUNDARY CONDITIONS

## DETERMINATION OF THE INTERFACE BOUNDARY CONDITIONS

To find the interface boundary conditions, the vapor velocity profile has to be established at least approximately. The momentum equation for an element of the vapor phase between  $y > y_s$  and  $y \rightarrow \infty$  is,

$$\mu_v \frac{\partial u_v}{\partial y} + u_v \frac{d}{dx} \left[ \int_0^{y_s} \rho_l u_l dy + \int_{y_s}^y \rho_v u_v dy \right] + \frac{d}{dx} \int_y^{\infty} \rho_v u_v^2 dy = 0 \quad (\text{A.1})$$

In dimensionless form, using the same development that led to equation (3.8),

$$\frac{\mu_v}{\mu_l} \frac{\partial u_v^+}{\partial y^+} + \frac{\rho_l}{\mu_l} y_s \frac{df}{dx} \left\{ u_v^+ \left[ 1 + \frac{\rho_v}{\rho_l} \int_0^{y^+} u_v^+ dy^+ \right] + \frac{\rho_v}{\rho_l} \left[ 2 - \frac{f \frac{dy_s}{dx}}{y_s \frac{df}{dx}} \right] \int_{y^+}^{\infty} u_v^{+2} dy^+ \right\} = 0 \quad (\text{A.2})$$

If  $\rho_v / \rho_l \ll 1$ , terms containing this ratio may be neglected. Using equation (3.6) yields:

$$\frac{\mu_v}{\mu_l} \frac{\partial u_v^+}{\partial y^+} = - \frac{k_l \Delta t D}{\mu_l \lambda (1 + Cs)} u_v^+ = -K u_v^+ \quad (\text{A.3})$$

The solution of this equation is:

$$u_v^+ = u_s^+ e^{\frac{\mu_l}{\mu_v} \kappa (1-y^+)} \quad (\text{A.4})$$

Now write the momentum equation for an element starting in the liquid surface

$$\mu_l \left. \frac{\partial u_l}{\partial y} \right|_s + u_s \frac{d}{dx} \int_0^{y_s} \rho_l u_l dy + \rho_v \frac{d}{dx} \int_{y_s}^{\infty} u_v^2 dy = 0 \quad (\text{A.5})$$

$$\begin{aligned} \left. \frac{\partial u_l^+}{\partial y^+} \right|_s + \kappa u_s^+ &= -\kappa \frac{\rho_v}{\rho_l} \left[ 2 - \frac{f \frac{dy_s}{dx}}{y_s \frac{df}{dx}} \right] \int_{y_s}^{\infty} u_v^{+2} dy^+ \\ &= u_s^{+2} \left[ 1 - \frac{f \frac{dy_s}{dx}}{2 y_s \frac{df}{dx}} \right] \frac{\mu_v \rho_v}{\mu_l \rho_l} \approx \frac{\mu_v \rho_v}{\mu_l \rho_l} \end{aligned} \quad (\text{A.6})$$

APPENDIX II

SAMPLE CALCULATIONS

## HORIZONTAL TUBE

RUN NO. 82

## Given Data:

$$r_o = 0.02384 \text{ ft.}$$

$$L = 2.354 \text{ ft.}$$

$$\sigma = 0$$

$$t_i = 141.8 \text{ }^\circ\text{F}$$

$$\Delta t = 23.2 \text{ }^\circ\text{F}$$

## Comparative Experimental Data:

$$t_o = 129.1 \text{ }^\circ\text{F}$$

$$Q_{lo} = 0.750 \times 10^{-4} \text{ ft}^3/\text{sec}$$

$$\frac{Q_{lo}}{\sqrt{gr_o^5}} = 0.1507$$

$$\phi_{cm} \approx 115^\circ$$

Fluid: Refrigerant-113

## Properties

$$\rho_l g = 92.17 \text{ lb/ft}^3$$

$$\rho_v g = 0.6904 \text{ lb/ft}^3$$

$$\lambda/g = 61.15 \text{ Btu/lb}$$

$$S = 0.0890$$

$$k_l = 1.293 \times 10^{-5} \text{ Btu/sec ft }^\circ\text{F}$$

$$\mu_l = 0.9150 \times 10^{-5} \text{ lbf sec/ft}^2$$

$$h_{in}/g = 99.62 \text{ Btu/lb}$$

$$h_{out}/g = 35.54 \text{ Btu/lb}$$

$$(\rho_l g)_{out} = 93.30 \text{ lbf/ft}^3$$

Assume  $\phi_{cm} = 120^\circ$ ,  $\theta_c = 60^\circ$ ,  $\phi = 120^\circ$ 

From equation (4.36):

$$\Omega = 2 \left[ \frac{91.48 \times (1.293)^3 \times 10^{-15} \times (0.02384)^3 \times (23.2)^3}{3 \times 0.9150 \times 10^{-5} \times (92.17 \times 61.15 \times 1.0605)^3} \right]^{\frac{1}{4}} \times 1.240 \times 1.564$$

$$= 0.3375 \times 10^{-4} \text{ ft}^3/\text{sec ft}$$

$$\frac{\Omega L}{\sqrt{gr_o^5}} = \frac{0.3375 \times 10^{-4} \times 2.354}{\sqrt{32.17 \times (0.02384)^5}} = 0.1596$$

$$\frac{\Omega^2 L^2}{gr_o^5} = 0.02545$$

$$\frac{\mu_e}{\rho_e \Omega} = 0.0946$$

From Figure 7.1:  $\phi_c = 106^\circ$ ,  $\theta_c = 53^\circ$ ,  $\delta = 127^\circ$

Integrating equation (4.42) from  $z^+ = 1$  to  $z^+ = 0.8$  yields on the right hand side the terms of equation (4.43):

$$I \quad \sigma = 0$$

$$II \quad -0.001417 \times 133.4 \times 0.02545 \times 98.7 \times \frac{0.79864}{(2.6972)^2} \times (0.008) = -0.000417$$

$$III \quad -1.125 \times 0.02545 \times 0.0946 \times \frac{1}{(0.240)^2} \times (0.64 - 1) = 0.01690$$

$$IV \quad 133.4 \times 0.02545 \times \frac{0.4444}{(2.6972)^2} \left[ 0.04 - 0.001417 \times 98.7 \times \frac{0.008}{0.4473} \right] \\ = 0.00779$$

$$V \quad -2.67 \times \frac{1}{0.4444} \times 0.02545(0.64 - 1) = 0.05505$$

The left hand side becomes:

$$\left[ \frac{A_e s_c}{r_o^3} \right]_1^2 = \frac{A_e s_c}{r_o^3} \Big|_2 - 0.07214$$

Equating the two sides

$$\frac{A_e s_c}{r_o^3} \Big|_2 = 0.07214 - 0.000417 + 0.01690 + 0.00779 + 0.05505 \\ = 0.1514$$

Correspondingly,  $\phi_c \approx 125^\circ$ ,  $\theta_c = 62.5^\circ$ ,  $\phi = 117.5^\circ$

Following the same procedure yields:

$$\text{from } z^+ = 0.8 \text{ to } z^+ = 0.5 \quad \phi_c = 142^\circ, \theta_c = 71^\circ, \phi = 109^\circ$$

$$\text{from } z^+ = 0.5 \text{ to } z^+ = 0.2 \quad \phi_c = 158^\circ, \theta_c = 79^\circ, \phi = 101^\circ$$

$$\phi_m \approx 113 \quad \phi_m \text{ assumed} = 120^\circ$$

Assumed value of  $\phi_m$  is satisfactory.

The heat transfer coefficient can be calculated from equation (3.23)

or by the following equivalent relation:

$$h_m = \frac{\Omega \rho_e \lambda (1 + 0.68 S)}{2 \pi r_o \Delta t} = \frac{0.3375 \times 10^{-4} \times 92.17 \times 61.15 \times 1.0605}{2 \pi \times 0.02384 \times 23.2}$$

$$= 0.0580 \text{ Btu/sec ft}^2 \text{ }^\circ\text{F}$$

$$= 208.8 \text{ Btu/sec ft}^2 \text{ }^\circ\text{F}$$

$$h_{m(\text{experimental})} = \frac{Q_{e_o} \rho_{e_{out}} (h_{in} - h_{out})}{2 \pi r_o L \Delta t}$$

$$= \frac{0.750 \times 10^{-4} \times 93.30 \times (99.62 - 35.54)}{2 \pi \times 0.02384 \times 2.354 \times 23.2}$$

$$= 0.0560 \text{ Btu/sec ft}^2 \text{ }^\circ\text{F}$$

$$= 201.6 \text{ Btu/hr ft}^2 \text{ }^\circ\text{F}$$

Difference between heat transfer coefficients is 3.6%

Nusselt Number based on diameter is:

$$\frac{h_m d_o}{k_e} = \frac{0.0560 \times 0.04768}{1.293 \times 10^{-5}}$$

$$= 206.4$$

## INCLINED TUBE

RUN NO. 119

## Given Data:

$$r_o = 0.02384 \text{ ft.}$$

$$L = 2.354 \text{ ft.}$$

$$\sigma = 0.1736$$

$$t_i = 127.8 \text{ }^\circ\text{F}$$

$$\Delta t = 9.4 \text{ }^\circ\text{F}$$

## Comparative Experimental Data

$$t_o = 124.7 \text{ }^\circ\text{F}$$

$$Q_{lo} = 0.4955 \times 10^{-4} \text{ ft}^3/\text{sec}$$

$$\frac{Q_{lo}}{\sqrt{gr_o^5}} = 0.0995$$

$$\phi_{cm} \approx 58^\circ$$

Fluid: Refrigerant 113

## Properties:

$$\rho_{lg} = 94.41 \text{ lb/ft}^3$$

$$\rho_{vg} = 0.5496 \text{ lb/ft}^3$$

$$\lambda/g = 62.32 \text{ Btu/lb}$$

$$S = 0.0347$$

$$k_g = 1.332 \times 10^{-5} \text{ Btu/sec-ft-}^\circ\text{F}$$

$$\mu_g = 0.9941 \times 10^{-5} \text{ lbf/sec/ft}^2$$

$$h_{in}/g = 97.56 \text{ Btu/lb}$$

$$h_{out}/g = 34.54 \text{ Btu/lb}$$

$$(\rho_{lg})_{out} = 93.68 \text{ lb/ft}^3$$

Assume

$$\phi_{cm} \approx 58^\circ, \phi = 151^\circ, \theta_c = 29^\circ$$

$$\Omega = 2 \left[ \frac{92.86 \times (1.332)^3 \times 10^{-15} \times (0.02384)^3 \times (9.4)^3}{3 \times 0.9941 \times 10^{-5} \times (93.41 \times 62.32 \times 1.024)^3} \right]^{\frac{1}{4}} \times 1.240 \times 1.859$$

$$= 0.2057 \times 10^{-4} \text{ ft}^3/\text{sec-ft}$$

$$\frac{\Omega L}{\sqrt[5]{gr_o}} = \frac{0.2057 \times 10^{-4} \times 2.354}{\sqrt[5]{32.17 \times (0.02384)^5}}$$

$$= 0.0970$$

$$\frac{\Omega^2 L^2}{gr_o^5} = 0.00943$$

$$\frac{\mu_f}{\rho_c \Omega} = 0.1664$$

Substitute the above quantities together with the angle functions corresponding to the assumed depth into equation (4.43), and set the limits at  $z_1^+ = 0.5$  and  $z_2^+ = 1$ .

$$\text{I} \quad 98.7 \times 0.08212 \times \sigma \times (0.5) = 4.050 \sigma$$

$$\begin{aligned} \text{II} \quad & -0.001417 \times 170.0 \times 0.00943 \times \frac{98.7}{(3.060)^2} \times 0.48481 \times (-0.125) \\ & = 0.00145 \end{aligned}$$

$$\begin{aligned} \text{III} \quad & -1.125 \times 0.00943 \times \frac{0.1664}{(0.0811)^2} (1 - 0.25) \\ & = -0.2013 \end{aligned}$$

$$\begin{aligned} \text{IV} \quad & 170 \times 0.00943 \times \frac{0.08212}{(3.060)^2} (-0.25 + 0.001417 \times \frac{98.7}{0.490} \times 0.125) \\ & = -0.00301 \end{aligned}$$

$$\begin{aligned} \text{V} \quad & -2.67 \times \frac{0.00943}{0.08212} (1 - 0.25) \\ & = -0.2300 \end{aligned}$$

$$4.050 \sigma + 0.00145 - 0.2013 - 0.00301 - 0.2300 = 0$$

$$\sigma = 0.1069$$

Following the same procedure yields:

$$\theta_c = 30^\circ, \phi = 150^\circ \quad \sigma = 0.0824$$

$$\theta_c = 27^\circ, \phi = 153^\circ \quad \sigma = 0.1620$$

$$\theta_c = 25^\circ, \phi = 155^\circ \quad \sigma = 0.2658$$

$$\theta_c = 23^\circ, \phi = 157^\circ \quad \sigma = 0.454$$

Plot on chart of Figure (4.3) and read  $\phi = 153.3^\circ$  corresponding to

$$\sigma = 0.1736$$

Assumed value of  $\phi$  satisfactory

A maximum product of the other two coordinates (relation 4.44) is

1.874, and it occurs at about

$$\sigma_{\text{opt}} = 0.2$$

The heat transfer coefficient can be calculated from equation (3.23) or by the following, equivalent relation:

$$h_m = \frac{\Omega \rho_e \lambda (1 + 0.68 S)}{2\pi r_o \Delta t} = \frac{0.2057 \times 93.41 \times 62.32 \times 1.024}{2\pi \times 0.02384 \times 9.4}$$

$$= 0.0870 \text{ Btu/sec-ft}^2\text{-}^\circ\text{F}$$

$$= 313.2 \text{ Btu/hr-ft}^2\text{-}^\circ\text{F}$$

$$h_{m(\text{experimental})} = \frac{Q_{\text{to}} \rho_{\text{out}} (h_{\text{in}} - h_{\text{out}})}{2\pi r_o L \Delta t}$$

$$= \frac{0.4955 \times 10^{-4} \times 93.68 \times (97.56 - 34.54)}{2\pi \times 0.02384 \times 2.354 \times 9.4}$$

$$= 0.0883 \text{ Btu/sec-ft}^2\text{-}^\circ\text{F}$$

$$= 317.9 \text{ Btu/hr-ft}^2\text{-}^\circ\text{F}$$

Difference between heat transfer coefficients is 1.5%

Nusselt Number based on diameter is:

$$\frac{h_m d}{k} = \frac{0.0883 \times 0.04768}{1.332 \times 10^{-5}}$$

$$= 316.0$$

APPENDIX III

EXPERIMENTAL DATA

TABLE A-1  
EQUIPMENT DATA  
WATER ANALOGY EXPERIMENTS

Test Section

Material: Methacrylate plastic

Length: 54 in.

Mean internal diameter: 1.101 in.

Number of liquid feed locations: 12, equally spaced

Number of air bleed locations: 12, equally spaced

Pump

Eastern Industries, Model E-7, Monel Metal Pump with Ohmite  
Control Rheostat

Liquid used was distilled water

Note on all experimental data

There were a number of exploratory tests made both before and between actual test runs. Also, in some of the experiments errors or other difficulties were discovered. Each of these runs had an assigned number. In the following tables only those data are included which have direct and meaningful relation to the topics covered in the text.

TABLE A-2  
 FLOW DEPTH DATA  
 WATER ANALOGY EXPERIMENTS

Run No.	Flow Rate		Angle Subtended by Liquid $2\theta_c$ , Degrees	Location Distance from Outlet	Comments
	$Q_c$ ml/sec	$\frac{Q_c}{\sqrt{g r_o^5}}$			
2	11.70	0.1616	109.3	1.5	
3	21.28	0.2938	127.1	1.5	
4	39.26	0.5419	139.6	1.5

24.50	0.3382	Turbulent	
23.62	0.3260	Mostly Turbulent	$\frac{Q_c}{\sqrt{\text{gr}_c^5}} = 0.33$
24.00	0.3313	Turbulent	Equivalent Critical Reynolds Number $Re_c = 3,580$
Run No. 44			
15.44	0.2131	Laminar but Disturbed	Liquid was supplied uniformly
17.35	0.2395	Partly Laminar	through all input locations,
19.84	0.2739	Turbulent	including the one nearest to
19.26	0.2659	Turbulent	outlet
18.50	0.2554	Turbulent	Water temperature was 80.2 °F
18.88	0.2602	Turbulent	
17.23	0.2379	Partly Laminar	Transition point is at
17.94	0.2477	Turbulent	
			$\frac{Q_c}{\sqrt{\text{gr}_c^5}} = 0.24$
			Equivalent Critical Reynolds Number $Re_c = 2,830$

TABLE A-4  
EQUIPMENT DATA  
CONDENSATION EXPERIMENTS

Test Section

Material: Std. 5/8" o.d. Aerofin copper tubing

Length: 28.25 in.

Internal diameter:  $0.571 \begin{matrix} + 0.003 \\ - 0.000 \end{matrix}$  in.

Internal heat transfer area: 0.3527 ft<sup>2</sup>

Number of fins per inch: 8

Fin outside diameter: 1.375 in.

Fin thickness: 0.008 in.

Thermocouples

Materials: No. 30, Leeds & Northrup copper-constantan wires

Calibration:  $\frac{(\text{Emf})_{\text{std.}} - (\text{Emf})_{\text{obs.}}}{(\text{Emf})_{\text{obs.}}} = -0.00418$

Locations: One in the vapor stream entering test section; three pairs soldered into slots at the top and bottom of the tube at 1/6 L, 1/2 L, and 5/6 L distance along the tube; one directly behind bottom point at outlet end in the condensate stream discharging from test section; two movable junctions.

Potentiometer: Leeds & Northrup Semiprecision Potentiometer

Variacs: General Radio Company, Type 100-R  
General Radio Company, Type W5MT

Wattmeter: Weston Model 310, No. 3760

Leveling Instrument: Wild (Heerbrugg) Switzerland N2-59138

Liquid used was distilled Refrigerant-113

TABLE A-5

## NOMENCLATURE FOR HEAT TRANSFER DATA

$\sigma$	slope of tube
$t_r$	room temperature, °F
$t_i$	vapor entering temperature, °F
$t_o$	condensate discharge temperature, °F
$t_t$	average temperature at top of tube, °F
$t_b$	average temperature at bottom of tube, °F
$\Delta t$	mean temperature difference between vapor and wall, °F
$Q_1 / \sqrt{g r_o^5}$	dimensionless discharge flow rate
$\phi_{cm}$	mean central angle subtended by condensate, degrees
$S = \frac{c_p \Delta t}{\lambda}$	dimensionless temperature difference
$\frac{hd}{k_1}$	Nusselt number

Run No.	$\sigma$	$t_r$	$t_i$	$t_o$	$t_t$	$t_b$	$\Delta t$	$Q_1 \sqrt{gr}^5$	$\phi$ cm	Liquid Ramp	Waves	Ripples on Wall	$S \times 10^3$	$\frac{hd}{k_1}$

TABLE A-6  
DEFINITIONS OF SYMBOLS

$Q_0$	condensate discharge rate, ml/sec
$Q_0 / \sqrt{g r_0^3}$	dimensionless flow rate
$2\theta_c = \phi_c$	angle subtended by condensate, degrees
$\frac{L-z}{L}$	approximate dimensionless distance from outlet end, fraction of tube length

APPENDIX IV

COMPUTER PROGRAMS

## NOMENCLATURE FOR COMPUTER PROGRAM No. M 931-3

(In order of appearance)

P	$\bar{p} = y_s^3$
DPZ	$\Delta \bar{p}$ in z direction
DPX	$\Delta \bar{p}$ in $\phi$ (or x) direction
X	$\phi$
Y	$y_s$
GRAV	$\frac{g(\rho_e - \rho_v)}{r_o} \left[ \sin \phi \bar{p}_n^{1/3} \left( \frac{\partial \bar{p}}{\partial \phi} \right)_n + \bar{p}_n^{4/3} \cos \phi \right]$
SHEAR	$1.5 \bar{p}_n \frac{\partial \tau_v}{\partial z}$
R	$r_o$
DTEMP	$\Delta t$
GAMV	$\Gamma_v$
DZ	$\Delta z$
DPHI	$\Delta \phi$
M,N	constants to determine total arc and numbers to be printed
G	$g(\rho_e - \rho_v)$
VISLI	$3 \frac{\mu_e}{\rho_e}$
VISVA	$\mu_v$
COND	$k_e$
EVAP	$\lambda'$
HYD	$\frac{d_{hv} r_o}{A_v}$

Q	$\frac{2 \rho_v A^2}{r_o^4}$
F	K
MORE	code for indicating last set of input data
GAMIN	$\Gamma_{in}$
START, COUNT	codes for determining printing sequence
REV	$\overline{Re}_v$
A	$a_i$
B	$b_i$
GAMEXP	$\Gamma_v^{2+b_i}$
HYDEXP	$\left(\frac{d_{nv}}{A_v}\right)^{b_i}$
WISEXP	$\mu_v^{b_i}$
TAU	$\tau_v$
DRIVE	$\frac{3 \mu_e k_e \Delta t}{\rho_e \lambda'}$
CONST	initial $y_s$ of condensate layer
SUM	$\sum_i^M \frac{1}{y_s}$
DEGAM	$-\frac{d \Gamma_v}{dz}$
HEATL	$\Gamma_{in} \lambda' / 2 \pi r_o \Delta t = h_m L$
DNUSL	$\frac{h_m L}{k_e}$
