Problem 1: Brushless Machine  Note that we can write Magnetization as a Fourier Series:

\[ M(\theta) = \sum_{n=1}^{\infty} M_n \sin np\theta \]

where the harmonic components are:

\[ M_n = \frac{B_r}{\mu_0} \frac{4}{n\pi} \sin n \frac{\theta_{me}}{2} \sin n \frac{\pi}{2} \]

To get the remanent flux density \( B_r \), note that the energy product is \( W = \frac{B_r^2}{\mu_0} \), or

\[ B_r = \sqrt{4 \times 42 \times 10^6} = 12,961 \text{ gauss} = 1.2961 \text{T} \]

Then the Fourier series for flux density at the rotor surface is

\[ B_s = \sum_n B_n \sin p\theta \]

where

\[ B_n = \mu_0 M_n k_{gn} \]

and the expression for the ‘gap factor’ is a straightforward extrapolation of what is in the notes:

\[ k_{gn} = \frac{1}{1 - \left( \frac{R_k}{R_s} \right)^2np} \left[ \frac{np}{np + 1} \left( \frac{R_t}{R_s} \right)^{np+1} - \left( \frac{R_k}{R_s} \right)^{np+1} \right] + \frac{np}{np - 1} \left( \frac{R_t}{R_s} \right)^{np+1} \left[ 1 - \left( \frac{R_k}{R_s} \right)^{np-1} \right] \]

Voltage is (to within a fixed sign), using VLB:

\[ V_n = 2R\ell\Omega k_{ln} k_{pn} B_n \]

and the winding factors are the well known pitch and breadth factors. Details of the calculations are in the attached script. The results are shown in Figure 1, which shows the magnetization reconstructed from the Fourier Series (in this case, I have taken the series out to 35th space harmonic: your answer may have fewer or more terms). Figure 2 shows the magnetic flux density at the surface of the stator bore and Figure 3 shows the induced voltage.

The harmonic amplitudes of the first five interesting harmonics are:
Figure 1: Magnetization reconstructed from Fourier Series

6.685 Problem Set 9, Problem 1
Harmonic Number  1
Gap Factor       = 0.6817  Magnetization = 1.272e+06
Pitch Factor    = 0.9659  Breadth Factor = 0.9659
Frequency       = 1885    Flux Component = 1.09
Voltage Component = 368

Harmonic Number  3
Gap Factor       = 0.6684  Magnetization = 3.105e+05
Pitch Factor    = 0.7071  Breadth Factor = 0.7071
Frequency       = 5655    Flux Component = 0.2608
Voltage Component = 47.19

Harmonic Number  5
Gap Factor       = 0.6437  Magnetization = 6.818e+04
Pitch Factor    = 0.2588  Breadth Factor = 0.2588
Frequency       = 9425    Flux Component = 0.05515
Voltage Component = 1.337

Harmonic Number  7
Gap Factor       = 0.6102  Magnetization = -4.87e+04
Pitch Factor    = -0.2588  Breadth Factor = -0.2588
Frequency       = 1.319e+04  Flux Component = -0.03734
Voltage Component = -0.9054

Harmonic Number  9
Gap Factor       = 0.5712  Magnetization = -1.035e+05
Pitch Factor    = -0.7071  Breadth Factor = -0.7071
Frequency       = 1.696e+04  Flux Component = -0.07428
Voltage Component = -13.44
Operating Details:
Internal Voltage = 377.2 Terminal Voltage = 389.5
Terminal Current = 29.54 Output Power = 1.672e+04
Reactance = 2.555 Resistance = 0.1652
Efficiency = 0.9872 Power Factor = 0.981
Air-Gap L = 0.001175 Slot L = 0.000181

Problem 2: More Brushless Machines To get the useful current capability of this machine we first need to estimate slot area. This is done by, first, computing tooth width:

\[ w_t = \frac{2\pi (R + h_d)}{6\text{pm}} - w_{st} \]

where \( w_{st} \) is the 'slot top' width. Slot bottom width is then:

\[ w_{sb} = \frac{2\pi (R + h_d + h_s)}{6\text{pm}} - w_t \]

Slot area is just

\[ A_s = h_s \frac{w_{st} + w_{sb}}{2} \]

Total armature ampere-turns per phase is:

\[ NI = J_{apm} A_s \]

Internal flux per turn (fundamental) is:

\[ \Phi = \frac{2R_s \ell B_{s1} k_{p1} k_{b1}}{p} \]
Problem 9.1

and since this is a round rotor machine, torque rating is:

\[ T_e = \frac{3}{2}pNI\Phi \]

The two components of inductance are air gap, for which we use the fundamental:

\[ L_{ag} = \frac{3 \pi \mu_0 R\ell N_s^2 k_p^2 k_k^2}{2 \pi} \frac{2}{p^2 (g + h_m)} \]

and slot leakage:

\[ L_{st} = \mathcal{P}_{\text{slot}} 2\ell_p N_e^2 (4N_{\text{self}} + N_{\text{mut}}) \]

where the number of slots per pole per phase with both coil halves in the same slot is

\[ N_{\text{self}} = m - N_{sp} \]

and the number of slots per pole per phase with coil halves in slots with other phases is:

\[ N_{\text{mut}} = 2N_{sp} \]

and of course slot permeance per unit length is:

\[ \mathcal{P}_{\text{slot}} = \mu_0 \left( \frac{h_d}{w_d} + \frac{1}{3} \frac{h_s}{w_{st}} \right) \]

To find winding resistance we need, first, area for each wire. This is:

\[ A_w = \frac{\lambda_a A_s}{2N_e} \]
where \( \lambda_s \) is the winding space factor. We also need the length of each wire, which is

\[
\ell_w = 2N_a (\ell + \ell_e)
\]

The length of the end winding is taken as half the circumference of a circle: \( \ell_e = \pi C \) where the diameter of that circle is the distance along a cylinder at the midplane of the slot and over the coil throw:

\[
C = \frac{5 \pi}{6} \frac{p}{\rho} \left( R_s + h_d + \frac{1}{2} h_s \right)
\]

Then winding resistance is

\[
R_a = \frac{\ell_w}{\sigma A_w}
\]

To get short circuit current we take fundamental voltage which is just:

\[
E_a = \omega N_a \Phi
\]

and divide that by impedance of the stator:

\[
Z_s = j\omega (L_{ag} + Ls\ell) + R_a
\]

The short circuit current is shown in Figure 4

![Short Circuit Current Graph](image.png)

Figure 4: Short Circuit Current

The other elements of rating are contained in the Matlab screen output:

**Operating Details:**
- Internal Voltage = 360.8
- Terminal Voltage = 372.3
