(Received 18 April 2010; revised manuscript received 17 June 2010; published 11 August 2010)

The impact of oxygen deficiency on physical properties of  $\text{Na}_{2/3}\text{CoO}_{2-\delta}$  has been investigated. From the combined thermogravimetric, magnetic susceptibility, and synchrotron x-ray Laue diffraction studies, it is demonstrated that  $\text{Na}_{2/3}\text{CoO}_2$  shows no superlattice ordering due to Na ions; however  $\text{Na}_{2/3}\text{CoO}_{1.98}$ , which has the same Co valence as that of  $\text{Na}_{0.71}\text{CoO}_2$ , shows nearly identical magnetic and transport properties and the same simple hexagonal superlattice ordering of  $\sqrt{12}a$ . It is proposed that the Na ion ordering found in  $\text{Na}_{2/3}\text{CoO}_{1.98}$  is identical to the ideal  $\text{Na}_{0.71}\text{CoO}_2$  of large  $\sqrt{12}a \times \sqrt{12}a \times 3c$  superlattice but with additional Na vacancies which are bound to the oxygen defects at room temperature. We conclude that oxygen vacancies play a key role in stabilizing the superlattice structure and must be accounted for in its modeling.

**I. INTRODUCTION**

$P2\text{-Na}_x\text{CoO}_2$  (also called  $\gamma$  phase) is composed of alternating layers of Na and  $\text{CoO}_2$  with a hexagonal in-plane network that can be described by space group  $P6_3/mmc$ .<sup>1</sup> Na vacancy ordering has been an important subject both experimentally and theoretically following the discovery of rich phase diagram of  $\text{Na}_x\text{CoO}_2$ ,<sup>2</sup> from the A-type antiferromagnetic (AF) ordering for  $x \geq 0.75$ , to AF and metal-to-insulator transitions near  $x=0.5$ , and the superconductivity found in the hydrated sample of  $x \sim 1/3$ .<sup>3</sup> In particular, the discovery of Na superlattice described by the multivacancy cluster model proposed by Roger *et al.* has generated additional interest in the exploration of the origin of Na vacancy ordering and its impact on the title compound.<sup>4,5</sup>

We have demonstrated that the particularly stable phases found near 0.71, 0.50, 0.33, and 0.25 also show sharp drop of the Na atom diffusion coefficients at room temperature.<sup>6</sup> However, it is quite surprising that the commonly predicted stable phases near  $x=3/4$  and  $2/3$  do not exist, as revealed by our single-crystal electrochemical deintercalation studies at room temperature. The Na superlattice as a result of Na ion ordering has been solved satisfactorily for  $x \sim 0.833$ , 0.820, 0.77, and 0.71 so far, based on Na multivacancy model of divacancy, trivacancy (T), and quadrivacancy (Q) cluster ordering.<sup>5-9</sup> For example,  $x=0.71$  is composed of alternating Na layers with trivacancy and quadrivacancy clusters ordered in a large simple hexagonal superlattice of size  $\sqrt{12}a$ .<sup>5,8</sup> The implication of such Na vacancy ordering has helped us understand the origin of small cross sections of the Fermi surface hole pockets observed by Shubnikov de Haas oscillation and the intriguing coexistence of metallic conductivity with Curie-Weiss behavior. This led us to propose that the Na vacancy ordering creates one special partial localization environment for the doped holes, i.e., part of the charge is localized near the vacancy center and the rest are itinerant throughout the vacancy-free region. Similar conclusion has been drawn based on <sup>59</sup>Co and <sup>23</sup>Na NMR in a sample of

nominal stoichiometry  $\text{Na}_{0.75}\text{CoO}_2$  as well, i.e., neither charge disproportion nor uniform average valence but an intermediate configuration should be used to describe this unique type of charge distribution.<sup>10</sup>

While Na vacancy is unavoidable for  $\text{Na}_x\text{CoO}_2$  samples prepared under ambient pressure, even under pure oxygen environment, the most probable Na content for samples prepared using solid-state reaction is usually in the range of 0.75–0.85.<sup>11</sup> Different vacancy ordering patterns for  $x=2/3$  have been proposed based on density-functional theory calculations.<sup>12,13</sup> However, single-crystal diffraction studies on  $\text{Na}_x\text{CoO}_2$  have not revealed any signature of Na ion ordering for  $x=2/3$ .<sup>6</sup> On the other hand, Platova *et al.* have proposed based on NMR and x-ray diffraction results, that a simple hexagonal superlattice of  $\sqrt{12}a$  exists in  $\text{Na}_{2/3}\text{CoO}_2$  where powder sample were carefully prepared under oxygen environment at 700 °C and quenched.<sup>14</sup> The proposed microscopic structure is very different from the trivacancy and quadrivacancy layer model we proposed for  $\text{Na}_{0.71}\text{CoO}_2$ . It is very surprising that the physical properties of their samples are very similar to ours despite the difference in Na concentration and their proposed superlattice size is identical to that found in  $\text{Na}_{0.71}\text{CoO}_2$  based synchrotron x-ray Laue and electron-diffraction studies on single-crystal sample with electrochemically fine-tuned  $x$ .<sup>5,8</sup> We have pointed out previously that the controversy could have resulted from differences in oxygen content,<sup>8</sup> i.e., the identical  $\sqrt{12}a$  simple hexagonal superlattice is a result of identical average Co valence between  $\text{Na}_{0.71}\text{CoO}_2$  and  $\text{Na}_{2/3}\text{CoO}_{1.98}$ . Herein, we provide conclusive evidence to resolve the controversy regarding the  $\sqrt{12}a$  superlattice ordering observed in  $x=2/3$ . It turns out that oxygen content plays an important factor that cannot be ignored when discussing all related physical properties in the  $\text{Na}_x\text{CoO}_{2-\delta}$  system. The nature of immobile and randomly distributed oxygen vacancy at room temperature renders the Na ion ordering more complicated, especially when the ordering along the  $c$  axis (staging) is considered as well.<sup>8,9</sup>

## II. EXPERIMENT

Single-crystal samples have been prepared from floating-zone method growth, following an additional electrochemical deintercalation technique as reported previously.<sup>7</sup> Oxygen environment with pressure higher than 8 atm has been kept in the optical floating-zone growth chamber to reduce Na loss due to evaporation and the generation of  $\text{Co}_3\text{O}_4$  impurity phase, in particular, to prevent the occurrence of oxygen deficiency. High-quality single-crystal  $\text{Na}_x\text{CoO}_2$  of  $x \sim 0.84$  could be obtained reproducibly starting from polycrystalline feed rod prepared from  $\text{Na}_2\text{CO}_3$  and  $\text{Co}_3\text{O}_4$  of Na:Co = 0.85:1 ratio. Samples with Na content of 0.71 and 2/3 were prepared from electrochemical deintercalation as reported previously,<sup>7</sup> where the as-grown crystal sample of  $\text{Na}_{0.84}\text{CoO}_2$  was used as working electrode, Pt as counter-electrode, and Ag/AgCl with sieved liquid junction as reference electrode. The applied voltages relative to Ag/AgCl reference electrode were 0.05 V and 0.20 V for the preparation of  $x=0.71$  and 2/3, respectively. Electron probe microanalysis (EPMA) has been performed on freshly cleaved inner surfaces to verify the chemical composition of each element. Perkin-Elmer thermogravimetric (TG)/differential thermal analysis (DTA) was used for thermal gravimetric analysis. Synchrotron x-ray Laue diffraction for superstructure investigation was performed at the NSRRC, Taiwan and magnetic-susceptibility measurement was done using Quantum Design superconducting quantum interference device vibrating-sample magnetometer (SQUID-VSM).

## III. RESULTS AND DISCUSSIONS

$\text{Na}_{0.71}\text{CoO}_2$  sample can be prepared through electrochemical deintercalation method precisely, as indicated by the diverging diffusion coefficient derived previously.<sup>6</sup> However, the target Na concentration for  $\text{Na}_{2/3}\text{CoO}_2$  is very hard to obtain precisely, partly because of its metastable nature. We have prepared sample with  $x=0.67 \pm 0.01$  and verified by both the x-ray lattice parameter analysis of linear  $c(x)$  extrapolation reported previously and EPMA to confirm this crucial concentration for this study. Additional oxygen control has been performed using TGA scan under various gas flows, including oxygen and air, up to 950 K. The as-prepared single-crystal samples of nearly oxygen deficiency-free samples for  $x=0.71$  and  $x=2/3$  have been ground into powder and go through additional annealing under TGA as shown in Fig. 1. We find that a significant weight loss occurs for  $x=2/3$  only near 700 K and this weight loss is recoverable under oxygen. On the other hand,  $x=0.71$  sample is stable at the same temperature range, whether the flowing gas is oxygen or air. The reversible weight loss for  $x=2/3$  sample near 700 K is about 0.30 wt %, which corresponds to an oxygen loss of 0.02. Interestingly, the Co valence of  $\text{Na}_{0.71}\text{CoO}_2$  and  $\text{Na}_{2/3}\text{CoO}_{1.98}$  are identical, and this thermal analysis suggests that the most stable average Co valence is near +3.29. To prepare oxygen-deficient  $\text{Na}_{2/3}\text{CoO}_{1.98}$  single-crystal sample for further study, we annealed the as-prepared  $\text{Na}_{2/3}\text{CoO}_2$  single-crystal sample at 700 K for 12 h and quenched, similar to the method used by Platova *et al.* on their powder sample.<sup>14</sup> We believe that the powder sample

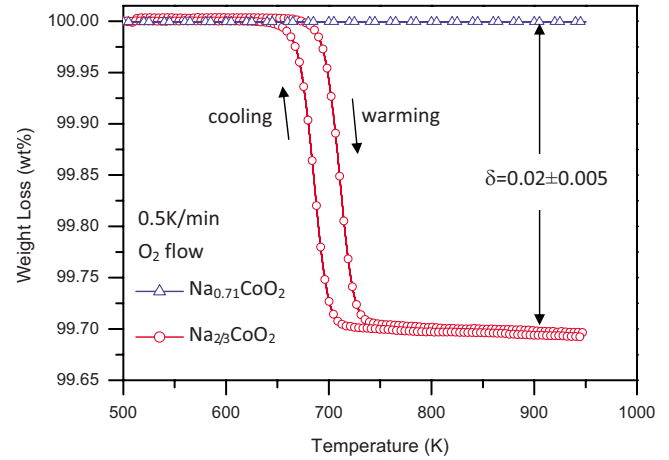

FIG. 1. (Color online) TGA scan for  $\text{Na}_{0.71}\text{CoO}_2$  and  $\text{Na}_{2/3}\text{CoO}_2$  single crystal prepared by electrochemical technique. The scan has been done with warming/cooling rate of 0.5 K/min in an oxygen environment.

studied by Platova *et al.* has an oxygen-deficiency level about 0.02 as described above.

It is instructive to compare the Laue diffraction patterns of  $\text{Na}_{0.71}\text{CoO}_2$ ,  $\text{Na}_{2/3}\text{CoO}_2$ , and  $\text{Na}_{2/3}\text{CoO}_{1.98}$  as shown in Fig. 2. The Laue pattern of  $\text{Na}_{0.71}\text{CoO}_2$  shows perfect superlattice of  $\sqrt{12}a$  as reported previously.<sup>5</sup> The superstructure of  $\text{Na}_{0.71}\text{CoO}_2$  has been modeled to be composed of alternating layers of sodium trivacancy (T) and quadrivacancy (Q) clusters ordered in simple hexagonal shape.<sup>5</sup> Additional structure refinement suggests that these alternating layers of TQTQTQ stacking has a  $3c$  periodicity described by a right-hand screw symmetry advanced Na trimers along the  $c$  axis.<sup>8</sup> While  $\text{Na}_{2/3}\text{CoO}_2$  shows no superlattice formation, as indicated in Fig. 2(b),  $\text{Na}_{2/3}\text{CoO}_{1.98}$  reveals a superstructure nearly identical to that of  $\text{Na}_{0.71}\text{CoO}_2$  in the reciprocal space. We note however, that detailed comparison of Laue patterns in Fig. 2 shows some systematic missing of superlattice diffraction planes for  $\text{Na}_{2/3}\text{CoO}_{1.98}$  as comparing with that of  $\text{Na}_{0.71}\text{CoO}_2$ , which suggests that even though these two samples possess identical superlattice size of  $\sqrt{12}a$ , subtle difference must exist as suggested by the NMR studies.<sup>15</sup> These results seem to suggest that similar Na ion ordering can be achieved as long as the average Co valence is close to +3.29.

Experimentally  $\text{Na}_{0.71}\text{CoO}_2$  has been shown to be the most stable phase as indicated by its significant sharp drop of the diffusion coefficient and the convincingly refined crystal structure of Na trivacancy and quadrivacancy cluster stacking of  $\sqrt{12}a \times \sqrt{12}a \times 3c$  superlattice ordering,<sup>5,6,8</sup> the observed identical superlattice size suggests that  $\text{Na}_{2/3}\text{CoO}_{1.98}$  can very well be a defect-type variation in the ideal  $\text{Na}_{0.71}\text{CoO}_2$ . To provide a more quantitative description to the current finding, let us take as an empirical fact that  $\text{Na}_{0.71}\text{CoO}_2$  with the trivacancy and quadrivacancy ordering is most stable. The  $\text{Na}_{2/3}\text{CoO}_{1.98}$  with oxygen vacancy means that for every 48 Co atoms, one oxygen is missing, i.e., one out of four  $\sqrt{12}a \times \sqrt{12}a$  supercell contains an oxygen vacancy. In order not to pay too much Coulomb energy for the  $\text{O}^{2-}$  vacancy, two additional Na vacancies will appear. Then

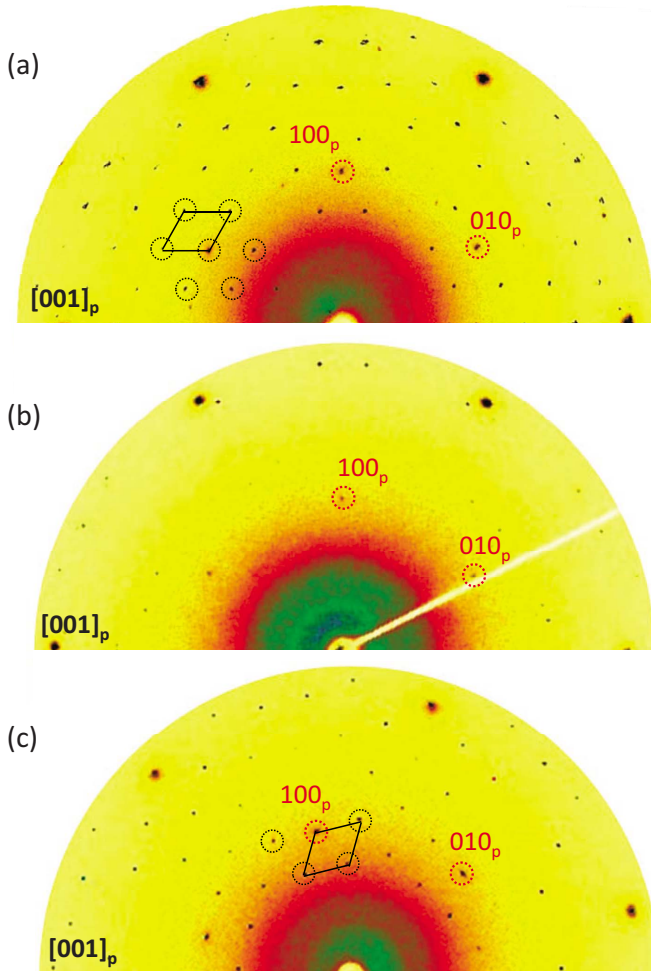

FIG. 2. (Color online) The Laue patterns for (a)  $\text{Na}_{0.71}\text{CoO}_2$ , (b)  $\text{Na}_{2/3}\text{CoO}_2$ , and (c)  $\text{Na}_{2/3}\text{CoO}_{1.98}$  taken along  $[001]$  direction at room temperature. The strong diffraction peaks are indexed as  $[100]$  and  $[010]$  of the primitive cell with size  $a$  constructed by Co ions, and the six superlattice peaks in hexagonal shape surrounding each primitive index correspond to a real lattice of size  $\sqrt{12}a$ .

on average the two trivacancy layers become quadrivacancies resulting in 8 Na per 12 cobalt atoms, i.e., we are led to a defect-type  $\text{Na}_{0.71}\text{CoO}_2$  structure of  $\text{Na}_{2/3}\text{CoO}_{1.98}$  stoichiometry. Another way of saying is that the oxygen vacancy is frozen in place randomly but the Na is mobile at room temperature. The additional missing Na (relative to 0.71) will be bound close to the missing oxygen in order to maintain the  $\sqrt{12}a$  superlattice. The reason for this stability presumably has large contribution from Madelung energy so it is at least partly electron driven. The superlattice found in  $\text{Na}_{2/3}\text{CoO}_{1.98}$  must be robust because it is prepared from a high-temperature quenching procedure of easy disorder introduction while  $\text{Na}_{2/3}\text{CoO}_2$  is prepared from a slow cooling process under oxygen atmosphere. We must note that oxygen vacancy is not mobile at room temperature while Na ion self diffusion is active above  $\sim 150\text{--}200$  K. The randomly distributed oxygen vacancy at the level of  $\sim 0.02$  per formula unit for  $\text{Na}_{2/3}\text{CoO}_{1.98}$  must be tolerated in order to allow Na layer to form a superstructure similar to that of  $\text{Na}_{0.71}\text{CoO}_2$ , it is difficult to understand within the proposal of Platova

FIG. 3. (Color online) Magnetic-susceptibility data for  $\text{Na}_{0.71}\text{CoO}_2$ ,  $\text{Na}_{2/3}\text{CoO}_2$ , and  $\text{Na}_{2/3}\text{CoO}_{1.98}$  in applied field of 1 T. The inset demonstrates the reliability of Curie-Weiss law fitting through difference between measured data and fitted equation of  $\chi_0 + C/(T - \theta)$  with parameters shown in Table I.

*et al.* for  $\text{Na}_{2/3}\text{CoO}_2$  why oxygen vacancies are needed to stabilize the superlattice structure. In any case, based on our findings it is clear that the role of oxygen deficiencies need to be accounted for in the modeling of the  $x=2/3$  material.

Magnetic-susceptibility measurement results are summarized in Fig. 3. The displayed data are powder average of the single-crystal measurement, i.e.,  $2/3\chi_{ab} + 1/3\chi_c$  without considering the minor correction of in-plane anisotropy. There is no magnetic anomaly found down to 2 K for all three samples. The Curie-Weiss behavior for a system with metallic property has long been a puzzle,<sup>2</sup> and it transforms from Curie-Weiss to Pauli-type behavior only when  $x$  is reduced to the level of nearly half-filled Na layer.<sup>7</sup> Based on our proposed Na vacancy cluster model published previously,<sup>5</sup> Na trivacancy and quadrivacancy cluster superlattice ordering could be responsible for the Curie-Weiss metal behavior, i.e., part of the doped holes are localized near the Na vacancy cluster center while the rest are itinerant. Both localized and itinerant electrons should contribute to the magnetic susceptibility. We propose that the total magnetic susceptibility should include contributions from temperature-independent core diamagnetic  $\chi^{core}$ , van Vleck paramagnetic  $\chi^{VV}$ , Pauli paramagnetic  $\chi^{Pauli}$ , and the spin susceptibility from localized spins which are tentatively described by a Curie-Weiss-type behavior of  $C/(T - \theta)$ . The Curie-Weiss behavior for all three samples has been fitted following an equation of  $\chi_0 + C/(T - \theta)$  in the range of 100–300 K quite satisfactorily as seen in the inset of Fig. 3, where  $C$  corresponds to the number of localized spins, Weiss temperature  $\theta$  indicates the mean-field average of the magnetic coupling strength among isolated spins, and  $\chi_0 = \chi^{core} + \chi^{VV} + \chi^{Pauli}$ . The fitted parameters for  $\chi(T)$  described by the Curie-Weiss law are shown in Table I. The fitted  $\chi_0$  values do not provide reliable physical meaning before each individual contribution can be analyzed. It is not surprising to find that  $C$  and  $\theta$  are about the same for  $\text{Na}_{0.71}\text{CoO}_2$  and  $\text{Na}_{2/3}\text{CoO}_{1.98}$ , which implies that the quantity and the coupling strength of isolated spins are nearly identical.  $\text{Na}_{2/3}\text{CoO}_2$  shows less isolated spins even

TABLE I. Summary of magnetic-susceptibility data analysis for  $\text{Na}_{2/3}\text{CoO}_2$ ,  $\text{Na}_{2/3}\text{CoO}_{1.98}$ , and  $\text{Na}_{0.71}\text{CoO}_2$  fitted using equation  $\chi_0 + C/(T-\theta)$  in the range of  $\sim 100\text{--}300$  K.

Sample	$\chi_0$ ( $\text{cm}^3/\text{mole}$ )	$C$ ( $\text{cm}^3 \text{K}/\text{mole}$ )	$\theta$
$\text{Na}_{2/3}\text{CoO}_2$	0.00049(3)	0.099(2)	-96(2)
$\text{Na}_{2/3}\text{CoO}_{1.98}$	0.00054(5)	0.109(2)	-60(2)
$\text{Na}_{0.71}\text{CoO}_2$	0.00034(2)	0.106(1)	-62(1)

though more holes are introduced compared with  $\text{Na}_{2/3}\text{CoO}_{1.98}$ . Clearly, formation of long-range Na multivacancy cluster ordering such as that demonstrated by the ideal  $\text{Na}_{0.71}\text{CoO}_2$ , is prohibited in  $\text{Na}_{2/3}\text{CoO}_2$ , unless oxygen vacancy is introduced.

The coexistence of local moments and itinerant electrons is a complicated many-body problem which is not fully understood. The data fitting using Curie-Weiss law plus Pauli is only a crude beginning. For instance, the  $C$  coefficient found for  $\text{Na}_{0.71}\text{CoO}_2$  corresponds to a  $S = \frac{1}{2}$  local moment per doped hole, which is clearly inconsistent with metallic behavior. We also acknowledge that another point of view has been proposed in the literature, i.e., the Curie-Weiss behavior signifies an almost ferromagnetic metal,<sup>16,17</sup> as described, for instance, by the self-consistent renormalized (SCR) spin-fluctuation theory.<sup>18</sup> However, in the standard SCR theory, the spin susceptibility saturates at low temperatures leading to Fermi-liquid behavior whereas in the present system  $\chi$  continues to rise down to 4 K (as seen in Fig. 3). Such a low Fermi-liquid scale is not expected without fine tuning. Furthermore, the resistivity exhibits a linear  $T$  dependence below 100 K and crossover to  $T^{1.3}$  below 4 K while the specific heat exhibits  $T \ln T$  dependence.<sup>19</sup> At the moment, neither the itinerant spin-fluctuation model nor the partial local moment picture is capable of explaining these anomalies. We leave this complicated and interesting issue open for future discussions. The main point of the present analysis is simply that the magnetic properties of  $\text{Na}_{0.71}\text{CoO}_2$  and  $\text{Na}_{2/3}\text{CoO}_{1.98}$  are very similar while that of  $\text{Na}_{2/3}\text{CoO}_2$  has distinctly different  $C$  and  $\theta$ .

We have also performed four-probe resistivity measurements on the  $\text{Na}_{0.71}\text{CoO}_2$ ,  $\text{Na}_{2/3}\text{CoO}_2$ , and  $\text{Na}_{2/3}\text{CoO}_{1.98}$  crystals as shown in Fig. 4. For  $\text{Na}_{0.71}\text{CoO}_2$ , the resistivity shows metallic behavior and drops with decreasing temperature. There is a crossover at about 100 K, below which the resistivity becomes practically linear in  $T$ . Similar behavior has also been observed in  $\text{Na}_{2/3}\text{CoO}_2$  and  $\text{Na}_{2/3}\text{CoO}_{1.98}$ . However, such deviation from the  $T$ -linear dependence at low temperature is evident and more significant in  $\text{Na}_{2/3}\text{CoO}_2$ . In addition, we note that the resistivity value is more than twice as large in  $\text{Na}_{2/3}\text{CoO}_2$  at low temperature, which suggests a shorter carrier lifetime due to a more disordered phase in  $\text{Na}_{2/3}\text{CoO}_2$ . These observations are in accord with the absence of Na superstructure ordering as mentioned earlier and also imply an intimate correlation between the Na ordering and the Co layer electronic structure.

Longitudinal magnetoresistance (LMR) and transverse magnetoresistance (TMR) were measured for the three

FIG. 4. (Color online) In-plane resistivities for  $\text{Na}_{0.71}\text{CoO}_2$ ,  $\text{Na}_{2/3}\text{CoO}_2$ , and  $\text{Na}_{2/3}\text{CoO}_{1.98}$ .

samples, where LMR and TMR were obtained under a magnetic field up to 14 T applied parallel and perpendicular to the  $\text{CoO}_2$  plane, respectively. The orbital magnetoresistance (OMR) was determined by subtracting TMR with LMR in order to exclude the spin-related contribution to the TMR. A comparison of LMR and OMR for the three samples is shown in Fig. 5. The OMR is positive for all three samples with quadratic magnetic field dependence as expected from orbital contribution, which is simply proportional to the square of carrier mobility.  $\text{Na}_{2/3}\text{CoO}_2$  shows smaller OMR than that of  $\text{Na}_{0.71}\text{CoO}_2$  and  $\text{Na}_{2/3}\text{CoO}_{1.98}$ , which infers a shorter carrier lifetime in a more disordered  $\text{Na}_{2/3}\text{CoO}_2$  as expected. On the other hand, LMR is typically derived from spin effect, where the negative LMR is most likely associated with the suppression of spin scattering due to the field

FIG. 5. (Color online) Longitudinal (LMR) and orbital (OMR) magnetoresistance for  $\text{Na}_{0.71}\text{CoO}_2$ ,  $\text{Na}_{2/3}\text{CoO}_2$ , and  $\text{Na}_{2/3}\text{CoO}_{1.98}$  are compared under magnetic field of 14 T.

alignment of localized moment. We find that the LMR in  $\text{Na}_{2/3}\text{CoO}_2$  is nearly half of that in  $\text{Na}_{0.71}\text{CoO}_2$  and  $\text{Na}_{2/3}\text{CoO}_{1.98}$  at low temperature, which suggests less spin scatterers in the system. Again, the main point is the similarity between  $\text{Na}_{0.71}\text{CoO}_2$  and  $\text{Na}_{2/3}\text{CoO}_{1.98}$  and their contrast with  $\text{Na}_{2/3}\text{CoO}_2$ . We also remark that the extraction of carrier density from Hall coefficient data is not possible because of its strong temperature dependence due to strongly correlated nature.

#### IV. CONCLUSIONS

In summary, using single-crystal samples of well-controlled oxygen and sodium content, we have provided strong evidence to resolve the controversy of superlattice ordering found in  $\text{Na}_x\text{CoO}_2$  of  $x=0.71$  and  $2/3$ . Synchrotron x-ray Laue diffraction results indicate that there is no sodium ordering in  $\text{Na}_{2/3}\text{CoO}_2$  at room temperature while  $\text{Na}_{2/3}\text{CoO}_{1.98}$ , which has identical Co valence to that of  $\text{Na}_{0.71}\text{CoO}_2$ , shows identical  $\sqrt{12}a$  simple hexagonal super-

structure to that of  $\text{Na}_{0.71}\text{CoO}_2$ , also with nearly identical magnetic and transport properties. These results imply that  $\text{Na}_{0.71}\text{CoO}_2$  with  $\sqrt{12}a \times \sqrt{12}a \times 3c$  superlattice is the most stable structure at this particular concentration while  $\text{Na}_{2/3}\text{CoO}_{1.98}$  of identical average Co valence possesses a nearly identical Na superstructure and magnetic properties with the help of oxygen defect generation. This proposed model is supported in part by the higher resistivity found in  $\text{Na}_{2/3}\text{CoO}_2$  without Na superstructure. Studies on Na ion ordering based on screened intersodium interaction without considering the involved oxygen deficiency could result in misleading prediction or interpretation.
