- A. How cells pull onto and deform the matrix to which they attach themselves.**
- B. Cell-matrix interactions control the spontaneous closure of wounds in organs.**
- C. What happens when regeneration is induced?**

## **C. What happens when regeneration is induced?**

- Closure of a defect by contraction (and scar synthesis) appears to block regeneration in the adult.**
- Certain ECM analogs that selectively lock contraction have been shown to induce partial regeneration in adults (skin, peripheral nerves, conjunctiva).**
- Under the same conditions, neither addition of growth factors nor of cell suspensions have blocked contraction nor have they induced regeneration.**

**Hypothesis: Regeneration requires selective blocking of contraction.**

# **A brief review of the obvious effects of closure by contraction**

# Isolated cell (fibroblast) contracts surface of thin silicone film, floating on oil. Buckling results.

# **Hypothesis: Regeneration requires selective blocking of contraction.**

## **Evidence supporting hypothesis (Chap. 8):**

- **Decrease in C coincided with increases in R (C and R are terms in defect closure rule).**
- **Delay in contraction kinetics coincided with induced regeneration.**
- **Suppression of closure by contraction (C) in spontaneously healing defects coincided with increased regeneration (R).**
- **Scar was abolished when contraction was inhibited.**
- **Suppression of contraction did not suffice to induce regeneration.**
- **Specificity of contraction blocking by ECM analogs.**

**Scar was abolished when contraction  
was inhibited.**

**See data in Table 8.1 above.**

# **Suppression of contraction did not suffice to induce regeneration.**

- **See data in Table 8.2 above.**
- **Addition of cortisone acetate (anti-inflammatory steroid), aspirin or prostaglandin inhibitor in the healthy rat wound delayed contraction; however, regeneration was not observed.**
- **Delayed contraction, but not regeneration, observed with impaired wounds (diabetic, or obese rats; infected wounds).**

# **Specificity of contraction blocking by ECM analogs.**

**Contraction was blocked only when each of the following structural features of ECM analogs was maintained within a narrow range (selective blocking):**

- average pore diameter**
- degradation rate**
- chemical composition**

# **Structural Features of ECM analogs**

**1. pore structure (ligand density)**

**2. macromolecular structure (ligand duration)**

Diagrams removed due to copyright considerations.

**3. chemical composition (ligand identity)**

**the length shift,  
 $\Delta L$ , measures  
the  
regenerative  
advantage of a  
device  
relative to the  
silicone  
tube standard.  
e.g.,  $\Delta L > 0$  is  
better than  
standard.**

# Conclusion

- **The data support the hypothesis that regeneration in adults is induced by selective blocking of contraction.**
- **Although blocking of contraction appears to be required, it is not sufficient to induce regeneration.**
