

# *Multi-echelon Inventory Systems*

- *Why?*
- *Issues and decisions?*
- *Models*

# *Why have a multi-echelon distribution system?*

- *Better service from regional locations*
- *Transportation economies*
- *Mixing functions*
- *Risk pooling over the manufacturing or procurement lead time*
- *Differentiated stocking and service policies*

# *Design and Planning Issues*

- *Number of echelons*
- *Number and location of distribution centers*
- *Stock location: what items to stock at each DC*
- *Replenishment policies – inventory & transportation; who serves whom*
- *Information systems*

# *Risk Pooling: Centralized Control*

- *Assume periodic review, base-stock policies*
- *Centralized control, with global information*
- *Cross-dock operation – no inventory held at a “central distribution center”*

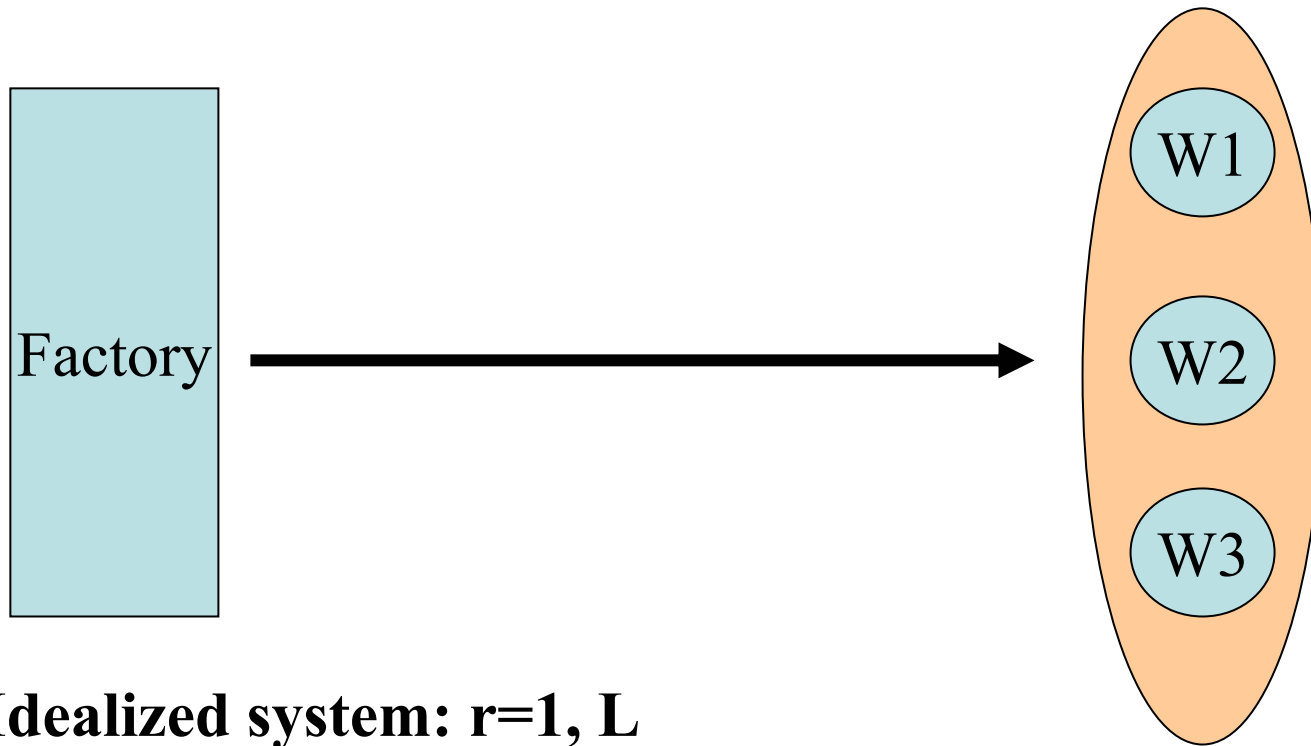

**Decentralized system:  $r = 1, L$**

**Safety stock at each warehouse proportional to  $\sigma_i \sqrt{L + 1}$**

**Total safety stock  $\approx z \sum_{i=1}^3 \sigma_i \sqrt{L + 1}$**

**Cycle stock? Pipeline stock?**

**Idealized system:  $r=1, L$**

**Total safety stock**

$$\approx z \sqrt{\sum_{i=1}^3 \sigma_i^2} \sqrt{L+1}$$

**Safety stock at each warehouse**

$$\approx z \frac{\sigma_i}{\sum_{i=1}^3 \sigma_i} \sqrt{\sum_{i=1}^3 \sigma_i^2} \sqrt{L+1}$$

**Cross-dock system:  $r = 1, L = L_1 + L_2$**

**Each period:**

- **System replenishment order =  $d_1 + d_2 + d_3$**
- **Allocate stock receipts to balance inventories**
- **Transship allocations**

# Cross-dock System

**Safety stock at each warehouse:**

$$\approx z \sqrt{\left( \frac{\sigma_j}{\sum_{i=1}^3 \sigma_i} \right)^2 L_1 \sum_{i=1}^3 \sigma_i^2 + (L_2 + 1) \sigma_j^2}$$

**Total safety stock:**

$$\approx z \sum_{j=1}^3 \sqrt{\left( \frac{\sigma_j}{\sum_{i=1}^3 \sigma_i} \right)^2 L_1 \sum_{i=1}^3 \sigma_i^2 + (L_2 + 1) \sigma_j^2}$$

|                      | <i>Total safety stock</i>                         |
|----------------------|---|
| <i>Decentralized</i> | $\approx \sigma n \sqrt{L + 1}$                   |
| <i>Idealized</i>     | $\approx \sigma \sqrt{n} \sqrt{L + 1}$            |
| <i>Cross-dock</i>    | $\approx \sigma n \sqrt{\frac{L_1}{n} + L_2 + 1}$ |

**n “identical” warehouses,  
each with standard deviation of demand =  $\sigma$**

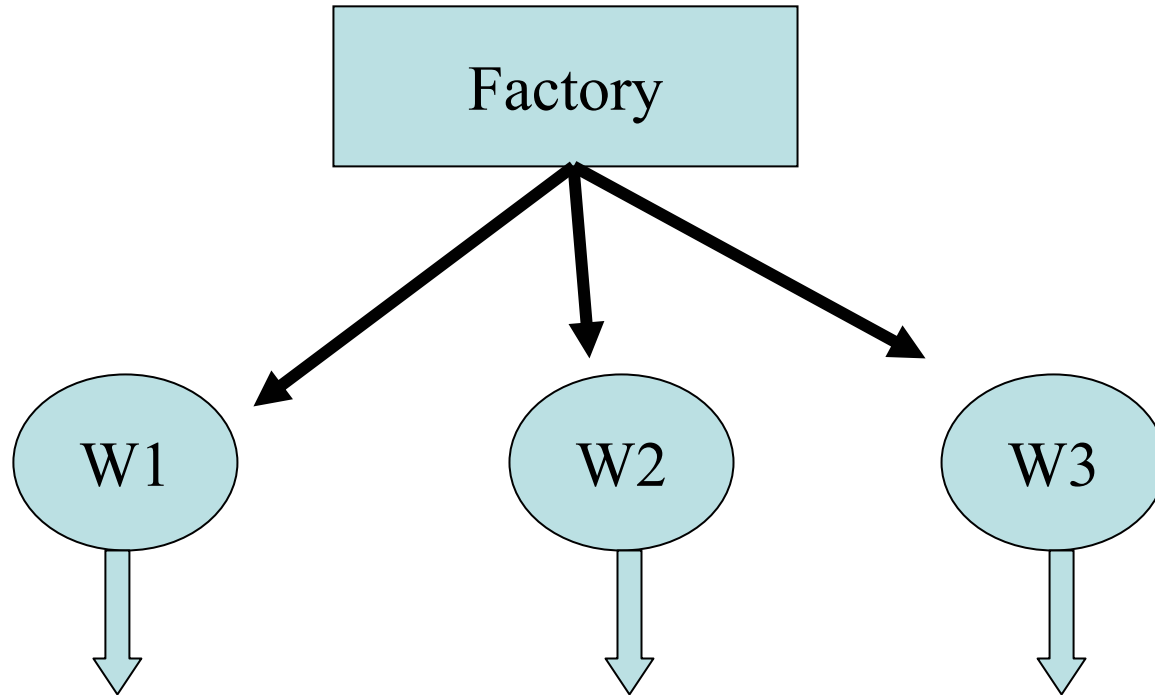

|        | $L_1=0$ | $L_1=2$ | $L_1=5$ | $L_1=8$ | $L_1=10$ | <i>Ideal</i> |
|--------|---------|---------|---------|---------|----------|--------------|
| $n=1$  | 166     | 166     | 166     | 166     | 166      | 166          |
| $n=2$  | 332     | 316     | 292     | 265     | 245      | 235          |
| $n=3$  | 497     | 466     | 415     | 357     | 312      | 287          |
| $n=5$  | 829     | 766     | 661     | 536     | 433      | 371          |
| $n=10$ | 1658    | 1517    | 1275    | 975     | 707      | 524          |

### **Safety stock**

**$L = 10, \sigma = 50, n$  warehouses with same  $\sigma$**

# Risk Pooling: Decentralized Control

- Assume periodic review, base-stock policies
- Decentralized control at warehouses, ordering on a central distribution center
- Central distribution center holds inventory, and operates without global information
- Central distribution center operates with high service level

**Independent warehouses**

**$r = 1$  week**

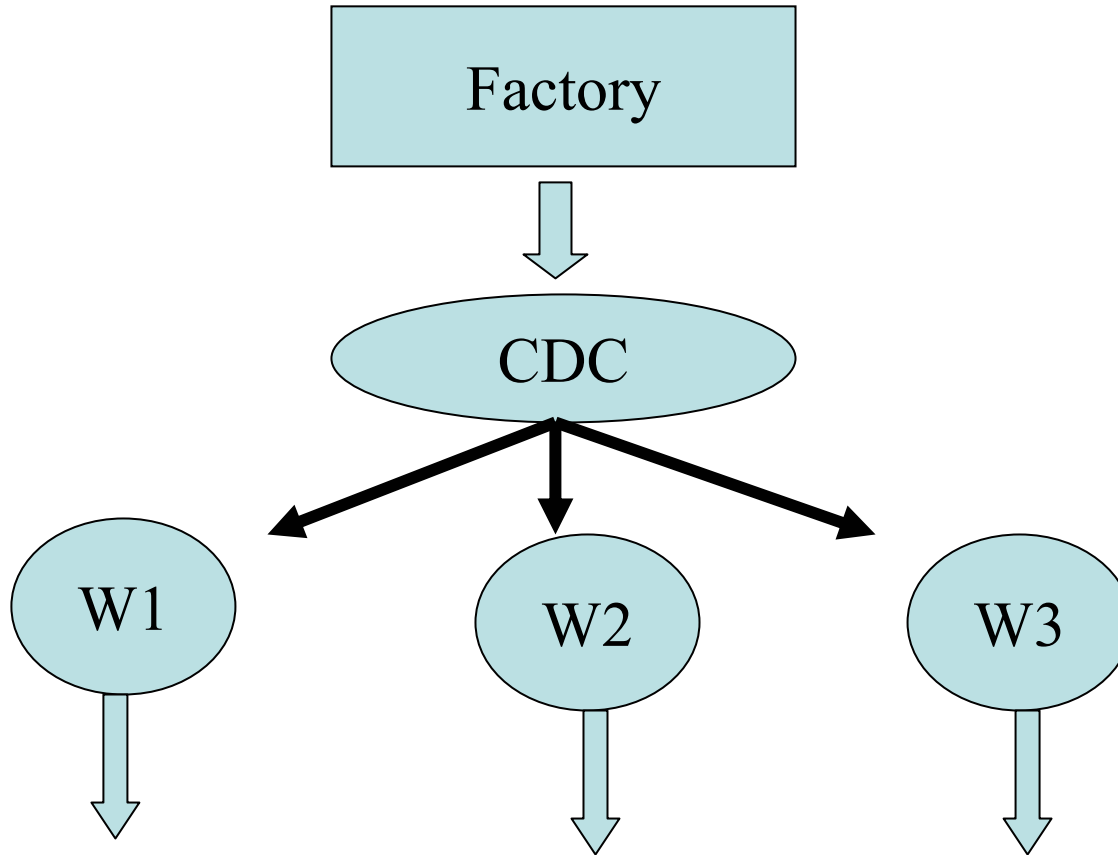

**$L = 7$  (production) + 1 (transportation) = 8 weeks**

**$E[D] = 500$  / week       $\sigma[D] = 50$  / week**

# *No CDC: How much safety stock?*

$$\text{At each W: } \approx \sigma \sqrt{r + L} = (50) \sqrt{1 + 8} = 150$$

$$\begin{aligned} \text{For } n \text{ independent warehouses: } &\approx n \sigma \sqrt{r + L} = 150n \\ &= 450 \text{ for } n = 3 \end{aligned}$$

**W:  $r = 1$  week**

**L = 1 week (transportation)**

**CDC:  $r = 1$  week**

**L = 7 weeks (production)**

**W:  $E[D] = 500$  / week**

**$\sigma[D] = 50$  / week**

# *CDC: How much safety stock?*

$$\text{At each W: } \approx \sigma\sqrt{r+L} = (50)\sqrt{1+1} = 71$$

$$\text{At CDC: } \approx \sigma\sqrt{n}\sqrt{r+L} = (50)\sqrt{3}\sqrt{1+7} = 245$$

$$\begin{aligned}\text{For system: } &\approx n\sigma\sqrt{r+L} + \sigma\sqrt{n}\sqrt{r+L} \\ &= (3)(50)\sqrt{2} + (50)\sqrt{3}\sqrt{1+7} \\ &= 212 + 245 = 457\end{aligned}$$

| <i># of Ws</i> | <i>One-echelon</i> | <i>Two-echelon</i> |
|----------------|--------------------|--------------------|
| <i>n=1</i>     | <i>150</i>         | <i>212</i>         |
| <i>n=2</i>     | <i>300</i>         | <i>342</i>         |
| <i>n=3</i>     | <i>450</i>         | <i>457</i>         |
| <i>n=4</i>     | <i>600</i>         | <i>566</i>         |
| <i>n=5</i>     | <i>750</i>         | <i>671</i>         |

# *Findings for Two-echelon Systems*

- *For high demand low cost items – CDC should not buffer: e. g. 50% fill rate target at CDC; 99% fill rate target at Ws*
- *For low demand high cost items – CDC should carry some safety stock, but usually less than normally assumed. Actual amount is very dependent on numbers.*
- *For some low demand items – stock only at CDC and use premium transport, or provide slower service*
